A Simple API for Grid Applications (SAGA)

Status of This Document

This document provides information to the grid community, proposing *the core components for an extensible Simple API for Grid Applications (SAGA Core API)*. It is supposed to be used as input to the definition of language specific bindings for this API, and by implementors of these bindings. Distribution is unlimited.

Abstract

This document specifies *the core components for the Simple API for Grid Applications (SAGA Core API)*, a high level, application-oriented API for grid application development. The scope of this API is derived from the requirements specified in GFD.71 ("A Requirements Analysis for a Simple API for Grid Applications"). It will in the future be extended by additional API extensions.

1 Introduction

This document specifies SAGA CORE, the Core of the *Simple API for Grid Applications*. SAGA is a high-level API that directly addresses the needs of application developers. The purpose of SAGA is two-fold:

1. Provide an **simple** API that can be used with much less effort compared to the vanilla interfaces of existing grid middleware. A guiding principle for achieving this simplicity is the *80-20 rule*: serve 80 % of the use cases with 20 % of the effort needed for serving 100 % of all possible requirements.
2. Provide a standardized, common interface across various grid middleware systems and their versions.

1.1 How to read this Document

This document is an API *specification*, and as such targets *at implementors of the API*, rather than its end users. In particular, this document should not be confused with a SAGA Users' Guide. This document might be useful as an API reference, but, in general, the API users' guide and reference should be published as separate documents, and should accompany SAGA implementations. *The latest version of the users guide and reference can be found at <http://saga.cct.lsu.edu>*

An implementor of the SAGA API should read the complete document carefully. It will *very likely be insufficient* unlikely be sufficient to extract the embedded SIDL specification of the API *hope to and* implement a SAGA-compliant API. In particular, the general design considerations in Section 2 give essential, additional information to be taken into account for any implementation *to be considered in order to be* SAGA compliant.

This document is structured as follows. This Section **focusses** on the formal aspects of an OGF recommendation document. Section 2 outlines the general design considerations of the SAGA API. Sections 3 and 4 contain the SAGA API specification itself. Section 5 gives author contact information and provides disclaimers concerning intellectual property rights and copyright issues, according to OGF policies. Finally, Appendix A gives illustrative, non-normative, code examples of using the SAGA API.

1.2 Notational Conventions

The key words **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **SHOULD NOT**, **RECOMMENDED**, **MAY**, and **OPTIONAL** are to be interpreted as described in RFC 2119 [6].

1.3 Security Considerations

As the SAGA API is to be implemented on different types of **grid** (and non-**grid**) middleware, it does not specify a single security model, but rather provides hooks to interface to various security models – see the documentation of the `saga::context` class in Section 3.6 for details.

A SAGA implementation is considered secure if and only if it fully supports (i.e. implements) the security models of the middleware layers it builds upon, and neither provides any (intentional or unintentional) means to by-pass these security models, nor weakens these security models' policies in any way.

2 General Design Considerations

This section *is addressing* *addresses* those aspects of the SAGA API specification *that are applicable* *common* to most or all of the SAGA packages as defined in Sections 3 and 4.

2.1 API Scope and Design Process

The scope and requirements of the SAGA API have been defined by OGF's *Simple API for Grid Applications Research Group* (SAGA-RG). The SAGA-RG has collected as broad as possible a set of use cases which has been published as GFD.70 [17]. *From these use cases, the requirements on a SAGA API have been derived. The requirements analysis has been published as GFD.71 [18] The requirements for the SAGA API were derived from this use cases document, an analysis of which has been published as GFD.71 [18]. For the actual API definition (this document), the SAGA-CORE Working Group (SAGA-CORE-WG) has been established. The formal specification and resulting document is the work of the SAGA-CORE Working Group which was spawned from the SAGA-RG.*

2.1.1 Requirements from the SAGA Requirement Analysis

The SAGA Requirement Analysis [18] lists the following functional and non-functional requirements *on* *of* the SAGA API: |

Functional Requirements

- Job submission and management should be supported by the SAGA API.
- Resource discovery should be supported by the SAGA API.
- Data management should be supported by the SAGA API.
- Efficient data access should be supported by the SAGA API.
- Data replication should be supported by the SAGA API.
- Persistent storage of application specific information should be supported by the SAGA API.
- Streaming of data should be supported by the SAGA API.
- Support for messages on top of the streaming API should be considered by the SAGA API.
- *Asynchronous notification should be supported by the SAGA API.* |

- Asynchronous notification should be supported by the SAGA API.
- Application level event generation and delivery should be supported by the SAGA API.
- Application steering should be supported by the SAGA API, but more use cases would be useful.
- GridRPC should be supported by the SAGA API.
- Further communication schemes should be considered as additional use cases are submitted to the group.
- Access to data-bases does not currently require explicit support in the SAGA API.

Non-functional Requirements

- Asynchronous operations should be supported by the API.
- Bulk operations should be supported by the API.
- The *exception handling* of the API should allow for *application level* error recovery strategies. |
- The SAGA API should be implementable on a variety of security infrastructures.
- The SAGA API should expose only a minimum of security details, if any at all.
- Auditing, logging and accounting should not be exposed in the API.
- Workflows do not require explicit support on API level.
- QoS does not require explicit support on API level.
- Transactions do not require explicit support *at the on* API level. |

2.1.2 Requirement Adoption Strategy

The use cases expressed the above requirements different levels of importance or urgency. This reflects the fact that some functionality is considered more important or even vital (like file access and job submission) while other functionality is seen as "nice to have" by many use cases (like application steering). Also, the group of active people in the SAGA specification process constitutes a specific set of expertise and interest – and this set is, to some extent, reflected in the selection of SAGA packages specified in this document.

For example, as *we received there were* no use cases from the enterprise user community, *and also had no nor was there any* active participation from that community in the SAGA standardization process, no enterprise specific API package is included here *We need to provide at least one example of the such a package.* This does not imply that we consider them unnecessary, but rather reflects *our the* wish *and need* to *orient derive* the API on real use cases, and to avoid the creation of an API *from perceived* use cases, and *from* half-baked expertise.

Scope of the SAGA API

As various sides expressed their need for the availability of a useful (i.e. implementable and usable) API specification as quickly as possible, the SAGA-CORE-WG decided to follow a two-phase approach. The SAGA API, as described in this document, covers all requirements that are considered both urgent and sufficiently well understood to produce an API. Addressing the other *the less urgent or well understood* requirements is deferred to future versions, or extensions, of the SAGA API. Based upon this reasoning, areas of functionality (from now *on* referred to as *packages*) that are included in SAGA API are the following:

- jobs
- files (and logical files)
- streams
- *remote procedure calls [19]*
- *auxiliary API's for*
 - session handle and security context
 - asynchronous method calls (tasks)
 - access control lists
 - attributes
 - monitoring
 - error handling

Possible extensions to be included in future SAGA versions or extensions are:

- steering and extended monitoring
- possibly combining logical/physical files (read on logical files)
- persistent information storage (see, e.g. the GAT Advert Service [2])
- GridCPR [11]
- task dependencies (simple work flows and task batches)
- extensions to existing classes, based on new use cases

The packages as listed above do not imply a hierarchy of API interfaces: all packages are motivated by their use cases; there is no split into 'lower level' and 'higher level' packages. The only exception is the group of auxiliary **APIs**, which is considered orthogonal to the non-auxiliary *maybe use the word "primary" in lieu of non-auxiliary; this also avoids the use of "core"* SAGA packages.

Dependencies between packages have been kept to a *minimal level* **minimum**, so as to allow each package to be used independently of any other; this *may* **will also** allow partially conformant API implementations (see below).

The term *CORE* in SAGA CORE refers to the fact that the scope of the API encompasses an initial required set of API objects and methods, which is **perceived** to be essential to the received use cases. *It is important to reiterate*, that the term, *again*, does not imply any hierarchy of API packages, such as CORE and SHELL packages etc. We will drop the use of *the* CORE when referring to the API and use the term in the context of the Working Group.

2.1.3 Relation to OGSA

The SAGA API specification effort has often been compared to, and seen as overlapping in scope and functionality to the OGSA standardization effort [10].

This is NOT correct. Reasons are the following: This perceived overlap in scope and functionality is misleading for the following reasons:

- OGSA applies to *the* service and middleware level.
SAGA applies to *the* application level.
- OGSA aims at service and middleware developers.
SAGA aims at application developers.
- OGSA is an architecture.
SAGA is an API.
- OGSA strives to be complete, and to fully cover any potential **grid service** in its architectural frame.
SAGA is by definition incomplete (80:20 rule), and aims *for coverage of* **to cover** the mostly used grid functionalities *on* **at the** application level. *, with NO ambition to be complete in any sense.*
- OGSA cannot sensibly interface to SAGA.
SAGA implementations can interface to (a subset of) OGSA compliant services (and in fact usually will do so).

For these and more reasons we think that SAGA and OGSA are complementary, but by no means **competitive**. The only commonality we are aware of is the *breadth* of both approaches: both OGSA and SAGA strive to cover more than one specific area of middleware and application functionality, respectively.

There have been discussions between the SAGA and OGSA groups *in of the* OGF, which tried to ensure that the SAGA specification does not imply any specific middleware properties, and in particular does not imply any state management which would contradict OGSA based middleware. Until now, we are not aware of any such conflict, and will continue to ensure seamless implementability on OGSA based middleware.

2.2 The SIDL Interface Definition Language

For the SAGA API, an object oriented (OO) approach was adopted, as it is easier to produce a procedural API from an OO API than the converse, and one of the goals of SAGA is to provide APIs which are as natural as possible in each implementation language. Advanced OO features such as polymorphism were avoided, both for simplicity and also to avoid complications when mapping to procedural languages.

The design team chose to use SIDL, the *Scientific Interface Definition Language* [4], for specifying the API. This provides a programming-language neutral representation of the API, but with well-defined syntax and clear mapping to implementation languages.

This document, however, slightly deviates from the original SIDL language definition. This section gives a brief introduction to SIDL, describes the respective deviations *we* used, and also contains a number of notes to implementors on how to interpret this specification.

SIDL, from the Babel project, is similar to COM and CORBA IDL, but has an emphasis on scientific computing, with support **for** multi-dimensional arrays, etc. Although the SAGA **specification** does not use these features extensively, the multilanguage scope of Babel for mappings from SIDL to programming languages appealed to the authors of this specification.

The key SIDL concepts used in this document are:

package:	specifies a name space (see note below)
interface:	set of methods
class:	stateful object and the associated set of methods
method:	service that can be invoked on a object
type:	constraint to value of method parameters

SIDL supports single inheritance of classes, and multiple inheritance of interfaces.

Method definitions have signatures, which define which parameters are accepted on method invocation. These parameters can be:

- **in**: input parameter, passed by value, assumed **constant**
- **out**: output parameter, passed by reference
- **inout**: input and output parameter, passed by reference

2.2.1 Deviations from SIDL in this Document

SIDL has the notion of packages, which are equivalent to Java packages or C++ name spaces. Packages are used in this specification, for the purpose of cross referencing different API sections. The packages are not *required* to show up in the **implementation's** class names or name spaces, apart from the top level 'saga' name space.

SIDL also has the notion of 'versions', which are actually required on packages. We do not use versions in this specification, as the specification itself is versioned, and we do not intend to introduce versioning on classes and interfaces.

SIDL allows **multi-dimensional** arrays, in the form `array<type,dim>`. As SAGA uses only one-dimensional arrays, this document uses the simplified notation `array<type>`.

SIDL defines a string to be a `char*`. We feel, however, that strings have more powerful and native expressions in some languages (such as C++, Perl and Java), and use `string` for these types. `char*`, conventionally used for binary inout memory chunks, is expressed in this document as `array<byte>`.

This specification defines all method calls as `void` (or rather does not specify any return type for method calls at all). Instead of explicit return values, we define **out** parameters, which are in SIDL parameters which are passed by reference. However, for this specification we expect language bindings to use the first specified output parameter as return value **of** function calls where appropriate, in particular for the synchronous versions of the function calls. The asynchronous versions will, by their very nature, stick to the **out** parameter scheme, as described in Section 3.10.

2.2.2 Default Parameter Values

This document, in several places, adds default values in the SIDL part of the API specification. It is up to the language bindings to exploit any native means for default parameter values. If this is not possible, the language binding CAN abstain from default parameter values. Also, if asynchronous method calls require additional parameters, which might affect the handling of default parameters in languages such as C and C++, the language binding CAN deviate from this document in that respect.

2.2.3 Constness

SIDL method parameters specified as `in` parameters are considered to be `const`, and MUST NOT be changed by the implementation. The SAGA language bindings SHOULD utilize language mechanisms to enforce constness of these parameters, if possible.

To our knowledge, SIDL does not allow the specification of constness `at` method level. This means, SIDL does not permit a specification of which methods must leave the state of the object unchanged. We considered the introduction of `const` modifiers, to achieve consistent semantics over different implementations. However, a short analysis of various implementation techniques convinced us that requiring method constness would raise significant limitations to SAGA implementors (e.g. for implementations with late binding), with no immediately visible advantage to SAGA users. Hence, we waived any method level constness requirements for now, but this topic might get picked up in future versions of the API, e.g. with respect to object serialization (which implies known and consistent object state *on at* serialization points).

2.2.4 Attributes and Metrics

The SIDL sections in this specification contain additional normative information which are inserted as SIDL comments. In particular these are definitions for *attributes* and *metrics*. *Format definitions and meaning for these entities and specifications* can be found in **Section 3.8 "SAGA Attributes Interface"** and Section 3.9 *"SAGA Monitoring Model"*, respectively.

2.2.5 Method Specification Details

All methods defined in the SIDL specification sections are further explained in the 'Specification Details' sections in this document. These details to

method specifications are *normative*. They are formatted as follows (example taken from the `saga::file` class):

|

```

- read
  Purpose: reads up to len_in bytes from the file into
           the buffer.
- Format:  read      (in   array<byte> buffer,
+ Format:  read      (inout buffer   buf,
!           in   int      len_in = -1,
           out  int      len_out);
  Inputs:  len_in:    number of bytes to be read
! InOuts:  buf:       buffer to read data into
  Outputs: len_out:    number of bytes successfully
                       read
+ PreCond: -
+ PostCond: - the data from the file are available in the
+             buffer.
+ Perms:    Read
  Throws:   NotImplemented
           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
! Notes:    - the actual number of bytes read into buffer
             is returned in len_out. It is not an error
             to read less bytes than requested, or in fact
             zero bytes, e.g. at the end of the file.
             - errors are indicated by returning negative
             values for len_out, which correspond to
!             negatives of the respective POSIX ERRNO error
             code.
             - the file pointer is positioned at the end of
             the byte area successfully read during this
             call.
!             - the given buffer must be large enough to
!             store up to len_in bytes, or managed by the
!             implementation - otherwise a 'BadParameter'
!             exception is thrown.
+             - the notes about memory management from the
+             buffer class apply.
!             - if the file was opened in write-only mode (i.e.
!             no 'Read' or 'ReadWrite' flag was given), this
!             method throws an 'PermissionDenied' exception.
!             - if len_in is smaller than 0, or not given,
!             the buffer size is used for len_in.
!             If that is also not available, a
!             'BadParameter' exception is thrown.
!             - similar to read (2) as specified by POSIX

```

The following sections are used in these detailed specifications of class methods:

Purpose:	the aim of the method
Format:	the SIDL prototype of the method
Inputs:	descriptions of in parameters
InOuts:	descriptions of inout parameters
Outputs:	descriptions of out parameters
PreCond:	conditions for successful invocation
PostCond:	effects of successful invocation
Perms:	permissions required for the method
Throws:	list of exceptions the method can throw
Notes:	other details

PreCond'tion: an example for a precondition is a specific object state. *An implementation MUST check these Preconditions, and MUST refuse to execute the method if they are not met, and throw an exception accordingly.*

PostCond'tion: an example for a postcondition is a changed object state. *An implementation MUST ensure that the postconditions are met upon successful method invocation, and MUST flag an error otherwise.*

Throws: *the exceptions listed in this section are the only SAGA exceptions which can be thrown by the method.*

Perms: *this section lists the permissions required to perform the method. If that permission is not available to the caller, a **PermissionDenied** exception MUST be thrown by the implementation.*

Notes: can contain, for example, references to the origin and use of the method, conditions on which exceptions are to be raised, semantic details of invocations, consistency implications of invocations, and more. *These Notes are normative!*

2.2.6 Inheritance

The SAGA API specification limits class inheritance to *single inheritance* – a class can, nevertheless, implement multiple interfaces. Similar to the original SIDL syntax, this document uses the qualifiers **extends** to signal inheritance relations of a class, and **implements** to signal an interface to be provided by a class.

Almost all SAGA classes implement the **saga::object** interface (which provides, for example, a unique instance id and the **saga::error_handler** interface), but the classes usually implement several other interfaces as well.

For inherited classes and implemented **interfaces** holds: if methods are over-

loaded (i.e. redefined with the same name), the semantics of the overloaded methods *from the base class* still **apply** (i.e. all **Notes** given on the detailed method description apply). *That This does also hold holds* for **CONSTRUCTORS** and **DESTRUCTORS**, and also, for example, for a `close()` which **is implicitly** called on the base class' destruction.

2.2.7 The SAGA Interfaces

For some SAGA objects, such as for `saga::logical_file`, SAGA interfaces, like the attribute interface, can allow access to remote entities. These methods should thus (a) also be available asynchronously, and (b) allow to apply the permission interface. However, asynchronous method calls and permissions make no sense for other, local SAGA objects, in particular on the SAGA Look-&-Feel level.

*Thus, instead of implementing the `saga::async` and `saga::permissions` interface in the various interfaces in general, this specification defines that SAGA implementations **MUST** apply the following rules:*

- *SAGA classes and interfaces, which implement the `saga::async` interface, and thus implement the SAGA task model, **MUST** also implement that task model for the methods defined in the following interfaces:*
 - `saga::attributes`
 - `saga::permissions`
 - `saga::monitorable`
 - `saga::steerable`
- *SAGA classes and interfaces, which implement the `saga::permissions` interface, and thus implement the SAGA permission model, **MUST** also implement that permission model for the methods defined in the following interfaces:*
 - `saga::attributes`
 - `saga::monitorable`
 - `saga::steerable`

2.3 Language Binding Issues

The abstract SAGA API specification, as provided by this document, is language independent, object oriented, and specified in SIDL. Normative bindings for specific languages, both object oriented and procedural, will be defined in additional documents.

This document contains several examples illustrating the use of the API, and these have naturally been shown in specific languages, such as C++. These examples should not be taken as normative, but merely as illustrative of the use of the API. When normative language bindings are available, these examples may be revised to reflect these bindings. In order to give an impression of the **Look-&-Feel** in other languages, Appendix A lists some of the examples in different languages. Again, Appendix A is illustrative, not normative.

Language bindings of the SAGA API shall provide the typical **Look-&-Feel** of the respective programming language. This comprises the syntax for the entities (objects, methods, classes, etc.), but also, to some degree, **semantic** details for which it makes sense to vary them with the programming language. We summarize the **semantic details** here.

- In this document, flags are denoted as bitfields (specifically, integer enums which can be combined by logical AND and OR). **This** is for notational convenience, and a language binding should use the most natural mechanism available.
- Language bindings MAY want to express array style arguments as variable argument lists, if that is appropriate.
- This document specifies file lengths, buffer lengths and **offsets** as **int** types. We expect implementations to use **suitably** large native data types, and to stick to language specific types where possible (such as **size_t** for buffer lengths in C, and **off_t** for file lengths in C). The SAGA language bindings MUST include the types to be used by the implementations. In particular, 64 bit types SHOULD be used if they are available.
- The SAGA **attribute** interface defines attribute keys to be strings. The SAGA monitorable interface defines metric names to be strings. At the same time, many attributes and metrics are predefined in this specification. In order to avoid typos, and improve interoperability between multiple implementations, we expect language bindings to exploit native mechanisms to have these **predefined** attributes and metric names specified as literal constants. For example, in C/C++ we would expect the following defines for the stream package (amongst others):

```
#define SAGA_METRIC_STATE      "state"
#define SAGA_STREAM_NODELAY   "nodelay"
```

- *Language bindings MAY define additional constants for special parameter values. For example, in C/C++ we would expect the following defines for timeout values (amongst others):*

```
#define SAGA_WAIT_FOREVER      -1.0
#define SAGA_NOWAIT            0.0
```

- Object lifetime management may be language specific. See Section 2.5.3.

- Concurrency control may be language specific. See Section 2.6.4.
- Thread safety may be language specific. See Section 2.6.5.

2.4 Compliant Implementations

A SAGA implementation MUST follow the SAGA API specification, and the language binding(s) for its respective programming language(s), both syntactically and semantically. *With respect to syntax, the language binding documents overrule this document, in case of contradictions.* This means that any method MUST be implemented with the syntax and with the semantics specified in this document *and the applicable language bindings*, or not be implemented at all (i.e. MUST then throw the `NotImplemented` exception).

The `NotImplemented` exception MUST, however, be used only in necessary cases, for example if an underlying `grid` middleware does not provide some capability, and if this capability can also not be emulated. The implementation MUST carefully document and motivate the use of the `NotImplemented` exception.

An implementation of the SAGA API is “*SAGA compliant*” if it implements all objects and methods of the SAGA API specification, possibly using the `NotImplemented` exception, as outlined above.

An implementation of the SAGA API is “*partially SAGA compliant*” if it implements only some packages, but implements those completely. It is, as with compliant implementations, acceptable to have methods that are not implemented at all (and thus throw a `NotImplemented` error).

All other implementations of the SAGA API are “*not SAGA compliant*”.

The SAGA `Look-&-Feel` classes and interfaces (*see Section 3*) (`exception`, `error_handler`, `object`, `session`, `context`, *permissions*, *buffer*, `attributes`, `callback`, `metric`, `monitorable`, `steerable`, `async`, `task`, and `task_container`) MUST be implemented completely for an implementation to be compliant. A partially compliant implementation MUST implement those SAGA `Look-&-Feel` classes and interfaces which are used by the packages the implementation *intends* to provide. A method in the SAGA `Look-&-Feel` classes and interfaces MUST NOT throw the `NotImplemented` exception.

Note that the exposure of additional (e.g. backend specific) classes, methods, or attributes within the SAGA API (e.g. within the `saga` name space) is considered to *break SAGA compliance*, unless *explicitly* allowed by this specification, as such extensions would bind applications to this specific implementation, and limit their portability, *which is the latter being* a declared goal of the SAGA approach.

The SAGA CORE Working Group will strive to provide, along with the language binding documents, compliance tests for implementors. It should also be noted that the SAGA language binding documents MAY specify deviations from the API syntax and semantics specified in this documents. In this case, the language binding specification supersedes this language independent specification. The language binding specifications MUST *, however,* strive to keep the set of differences to this specification as small as possible. |

2.4.1 Early versus late binding

An implementation may choose to use late binding to middleware. This means that the middleware binding might change between subsequent SAGA calls. For example, a `file.open()` might be performed via the HTTP binding, but a subsequent `read()` on this file might *fail, and instead* be performed with GridFTP. |

Late binding has some advantages in terms of flexibility and error recovery. However, it implies a certain amount of object state to be kept on client side, which might have semantic consequences. For example, a `read()` operation might fail on HTTP for some reasons, but might succeed via GridFTP. The situation might be reversed for `write()`. In order to allow alternating access via both protocols, the file pointer information (e.g. the file object state) must be held on client side.

It is left to a later experience document about the SAGA API implementations to discuss potential problems arising from early/late binding implementations, with respect to semantic conformance to the SAGA API specification. It should be noted here that method-level constness would represent a major obstacle for late binding implementations.

Late binding MUST NOT delay the check of error conditions if this is semantically required by the specification. For example, a `file.open()` should check for the existence of the file, even if the implementation may bind to a different middleware on subsequent operations on this file. |

2.5 Object Management

The API specification in Sections 3 and 4 defines various kinds of objects. Here, we describe generic design considerations about managing these objects.

2.5.1 Session Management

The specification introduces a `saga::session` object, which acts as session handle. A session thereby identifies objects and operations which are sharing information, such as security details. *Also*, objects and methods from different sessions *are guaranteed to not to MUST NOT* share any information. *, and are completely shielded from each other.* This will allow *an* application to communicate with different **grids** and VOs at the same time, or to assume different IDs at the same time. Many applications, however, will have no need for explicit session handling. For those cases, a default **SAGA** session is used if no explicit `saga::session` object is created and used.

Any SAGA object is associated with a session at creation time, by using the respective `saga::session` instance as first argument to the constructor. If the session argument is **omitted**, the object is associated with the default session. SAGA objects created from other SAGA objects (such as a `saga::file` instance created by calling `open()` on a `saga::directory` instance) inherit the **parent's** session. The remainder of the document refers to the default session instance as `theSession`.

A `saga::context` instance is used to encapsulate a virtual identity, such as a Globus certificate or an ssh key pair. Multiple context instances can be associated with one session, and only **that** context information **MUST** be used to perform any operation in this session (i.e. on objects associated with this session). If no `saga::context` instances are explicitly added to a SAGA session, the SAGA implementation **MAY** associate one or more default contexts with any new session, including the default session. In fact, the default session can **ONLY** use these default contexts.

2.5.2 Shallow versus Deep Copy

Copy operations **on** SAGA objects are, by default, shallow. This applies, for example, when SAGA objects are passed by value, or by assignment operations. Shallow copy means that the original object instance and the new (copied) instance share state. For example, the following code snippet

Code Example

```

1  saga::file f1 (url);           // file pointer is at 0
2  saga::file f2 = f1;           // shallow copy
3
4  cout << "f1 is at " << f1.seek (0, Current) << "\n";
5  cout << "f2 is at " << f2.seek (0, Current) << "\n";
6
7  f1.seek (10, Current);         // change state
8

```

```
9   cout << "f1 is at " << f1.seek (0, Current) << "\n";  
10  cout << "f2 is at " << f2.seek (0, Current) << "\n";
```

would yield the following output (comments added):

```
f1 is at 0  
f2 is at 0   -> shallow copy of f1  
  
f1 is at 10  -> state of f1 changes  
f2 is at 10  -> state of f2 changes too: it is shared
```

The SAGA API allows, however, to perform deep copies on all SAGA objects, by explicitly using the `clone()` method. The changed code snippet:

```
Code Example  
1   saga::file f1 (url);           // file pointer is at 0  
2   saga::file f2 = f1.clone();    // deep copy  
3  
4   cout << "f1 is at " << f1.seek (0, Current) << "\n";  
5   cout << "f2 is at " << f2.seek (0, Current) << "\n";  
6  
7   f1.seek (10, Current);         // change state  
8  
9   cout << "f1 is at " << f1.seek (0, Current) << "\n";  
10  cout << "f2 is at " << f2.seek (0, Current) << "\n";
```

would then yield the following output (comments added):

```
f1 is at 0  
f2 is at 0   -> deep copy of f1  
  
f1 is at 10  -> state of f1 changes  
! f2 is at 0 -> state of f2 did not change, it is not shared
```

SAGA language bindings MAY deviate from these semantics if (and only if) these semantics would be non-intuitive in the target language.

If a SAGA object gets (deeply) copied by the `clone` method, its complete state is copied, with the exception of:

- information about previous error conditions (*is not copied*, see Section 3.1),
- callbacks on metrics (*are not copied*, see Section 3.9).
- *the session the object was created in (is shallow copied, see Section 3.5),*

Not copying previous error conditions disambiguates error handling. *Not copying the session ensures that the same session is continued to be shared between objects in that session, as intended.* Not copying registered callbacks is required to ensure proper functioning of the callback invocation mechanism, as callbacks have an inherent mechanism to allow callbacks to be called *exactly* once. Copying callbacks would undermine that mechanism, as callbacks could be called more than once (once on the original metric, once on the copied metric).

Note that a copied object will, in general, point to the same remote instance. For example, the copy of a `saga::job` instance will not cause the spawning of a new remote job, but will merely create a new handle to the same remote process the first instance pointed to. The new object instance is just a new handle which is in the same state as the original handle – from then on, the two handles have a life of their own. Obviously, operations on one SAGA object instance may still in fact influence the copied instance, e.g. if `cancel()` is called on either one.

Note also, that the deep/shallow copy semantics is the same for synchronous and asynchronous versions of any SAGA method call.

2.5.3 Object State Lifetime

In general, the lifetime of SAGA object instances is defined as natively expected in the respective languages, so `it` is usually explicitly managed, or implicitly defined by scoping, or in some languages implicitly managed by garbage collection mechanisms.

The SAGA API semantics, in particular asynchronous operations, tasks, and monitoring metrics require, however, that the state of certain objects must be able to survive the lifetime of the context in which they `were` created. As state in these situations is shared with the original object instance, this may imply in some languages that the respective objects must survive as well.

In particular, object state **MUST** be available in the following situations:

- The state of a `saga::object` instance ***MUST*** be available to all tasks

created on this object instance.

- The state of a `saga::object` instance *MUST* be available to all metrics created on this object instance.
- The state of a `saga::session` instance *MUST* be available to all objects created in this session.
- The state of a `saga::context` instance *MUST* be available to all sessions this context instance was added to.
- *The state of the default session MUST be available to the first invocation of any SAGA API method, and SHOULD be available for the remaining lifetime of the SAGA application.*

Due to the diversity of lifetime management used in existing programming languages, this document can not prescribe a single mechanism to implement objects or object states that survive the context they were created in. It is subject to individual language binding documents to prescribe such mechanisms, and to define responsibilities for object creation and destruction, both for SAGA implementations and for application programs, in order to match requirements and common-sense in the respective languages.

The SAGA specification implies that object state is shared in the following situations:

- **an** asynchronous operation is invoked on an object, creating a task instance;
- a SAGA object is passed as argument to a (synchronous or asynchronous) method call.

Those method calls that deviate from these semantics denote **this** in their `PostConditions` (e.g. prescribe that a deep copy of state occurs).

2.5.4 Freeing of Resources and Garbage Collection

The destruction of objects in distributed systems has its own subtle problems, as has the interruption of remote operations. In particular it cannot be assumed that a destructor can both return timely *and* ensure the de-allocation of all (local and remote) resources. In particular, as a remote connection breaks, no guarantees whatsoever can be made about the de-allocation of remote resources.

In particular for SAGA tasks, which represent asynchronous remote operations, we expect implementations to run into this problem space, for example

if `cancel()` is invoked on this task. To have common semantic guidelines for resource de-allocation, we define:

1. On explicit or implicit object destruction, and on explicit or implicit interruption of synchronous and asynchronous method invocations, SAGA implementations MUST make a best-effort attempt to free associated resources immediately¹.
2. If the immediate de-allocation of resources is not possible, for whichever reasons, the *respective interrupting or destructing* methods MUST return immediately, but the resource de-allocation MAY be delayed indefinitely. However, as of (1), the best effort strategy to free these resources eventually MUST stay in place.
3. Methods whose semantics depend on successful or unsuccessful de-allocation of resources (such as `task.cancel()` or `file.close()`) allow for an optional `float` argument, which defines a timeout for this operation (*see Section 2.6.3*). If resource de-allocation does not succeed within this timeout period, a `NoSuccess` exception MUST be thrown. Negative values imply to wait forever. *A* value of zero (the default) implies that the method can return immediately; *no exception is thrown*, even if some resources could not be de-allocated. In any case, the best-effort policy as described above applies.

SAGA implementations MUST motivate and document any deviation from this behaviour. See also Section 2.4 on compliant implementations.

2.5.5 Destructors and `close()`

Destructors are implying a call to `close()` of the respective object (if a `close()` is defined for that class), unless, as described above, tasks are still using the respective resources – *then the close is delayed until the last of these tasks is destroyed (see 2.5.3)*. It must be noted that, unlike when using a direct call to `close()`, exceptions occurring on such an implicit `close()` cannot be communicated to the application: throwing exceptions in destructors is, in general, considered unclean design, and is in many languages outright forbidden. Thus, an explicit `close()` should be used by the application if feedback about eventual error conditions *are is* required. Otherwise, an implicit `close()` on object destruction will silently discard such error conditions (exceptions).

¹*Immediately* in the description above means: within the expected response time of the overall system, but not longer.

2.6 Asynchronous Operations and Concurrency

In this section, we describe the general design considerations related to asynchronous operations, concurrency control, and multithreading.

2.6.1 Asynchronous Function Calls

The need for asynchronous calls was explicitly stated by the use cases, as reasonable synchronous behaviour cannot always be expected from **grids**. The SAGA task interface allows the creation of an asynchronous version of each SAGA API method call. The SIDL specification lists only the synchronous version of the API methods, but all *classes* implementing the task interface **MUST** provide the various asynchronous methods as well. Please see Section 3.10 for details on the task interface.

2.6.2 Asynchronous Notification

Related to this topic, the group also discussed the merits of callback and polling mechanisms and agreed that a callback mechanism should be used in SAGA to allow for asynchronous notification. In particular, this mechanism should allow for notification on the completion of asynchronous operations, i.e. task state changes. However, polling for states and other events is also supported.

2.6.3 Timeouts

Several methods in the SAGA API support the synchronization of concurrent operations. Often, those methods accept a **float** timeout parameter. The semantics of *that this* parameter ***MUST be*** as follows:

```
timeout < 0.0  - wait forever
timeout = 0.0  - return immediately
timeout > 0.0  - wait for this many seconds
```

These methods *do **MUST not*** cause a **Timeout** exception as the timeout period passes, but ***MUST*** return silently. For **a** description of the **Timeout** exception, see Section 3.1.

The various methods often define *different* default timeouts. For timeouts on **close()** methods, the description of resource **de-allocation** policies in Section 2.5.4 is also relevant.

2.6.4 Concurrency Control

Although limited, SAGA defines a de-facto concurrent programming model, via the task model and the asynchronous notification mechanism. Sharing of object state among concurrent units (e.g. tasks) is intentional and necessary for addressing the needs of various use cases. Concurrent use of shared state, however, requires concurrency control to avoid unpredictable behavior.

(Un)fortunately, a large variety of concurrency control mechanisms exist, with different programming languages lending themselves to certain flavors, like object locks and monitors in Java, or POSIX mutexes in C-like languages. For some use cases of SAGA, enforced concurrency control mechanisms might be both unnecessary and counter productive, leading to increased programming complexity and runtime overheads.

Because of these constraints, SAGA does not enforce concurrency *control* mechanisms on its implementations. Instead, it is the responsibility of the application programmer to ensure that her program will execute correctly in all possible orderings and interleavings of the concurrent units. The application programmer is free to use any concurrency control scheme (like locks, mutexes, or monitors) in addition to the SAGA API.

2.6.5 Thread Safety

We expect implementations of the SAGA API to be thread safe. Otherwise, the SAGA task model would be difficult to implement, and would also be close to useless. However, we acknowledge that specific languages might have trouble with (a) expressing the task model as it stands, and (b) might actually be successful to implement the API single threaded, and non-thread safe. Hence, we expect the language bindings to define if compliant implementations in this language **MUST** or **CAN** be thread safe – with **MUST** being the default, and **CAN** requiring good motivation.

2.7 State Diagrams

Several objects in SAGA have a *state* attribute or metric, which implies a state diagram for these objects. That means, that instances of these objects can undergo well defined state transitions, which are either triggered by calling specific methods on these object instances, or by calling methods on other object instances affecting these instances, or are triggered by internal events, for example by backend activities. State diagrams as shown in Figure 1 are used to define the available states, and the **allowed** state transitions. These diagrams are *normative*.

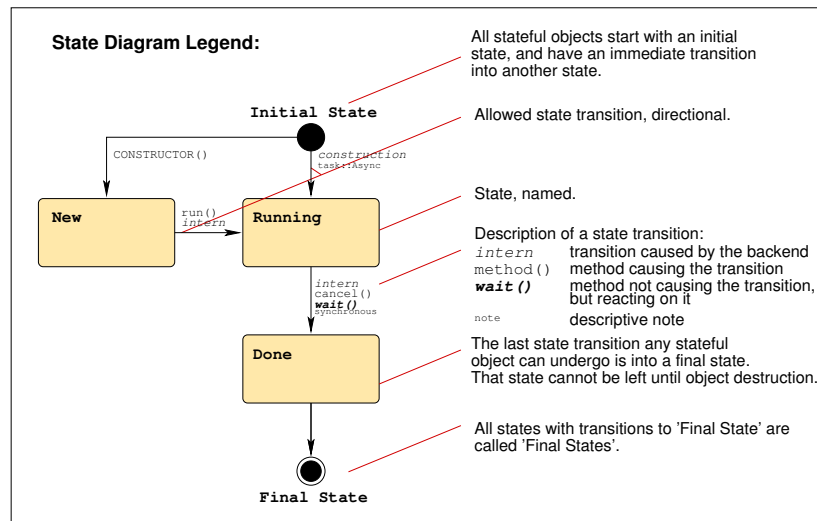

Figure 1: The SAGA state diagrams follow the notations shown here.

2.8 Execution Semantics and Consistency Model

A topic related to concurrency control concerns execution semantics of the operations invoked via SAGA's API calls. Unlike Section 2.6, here we are dealing with the complete execution "chain," reaching from the client API to the server side, based on whichever service or middleware layer is providing access to the server itself.

SAGA API calls on a single service or server can occur concurrently with (a) other tasks from the same SAGA application, (b) tasks from other SAGA applications, or also (c) calls from other, independently developed (non-SAGA) applications. This means that the user of the SAGA API should not rely on any specific execution order of concurrent API calls. However, implementations **MUST** guarantee that a synchronous method is indeed finished when the method returns, and that an asynchronous method is indeed finished when the task instance representing this method is in *Finished or Done* a *final* state. Further control of execution order, if needed, has to be enforced via separate concurrency control mechanisms, preferably provided by the services themselves, or on application level.

Most SAGA calls will invoke services that are remote to the application program, hence becoming vulnerable to errors caused by remote (network-based) invocation. Therefore, implementors **SHOULD** strive to implement "At Most Once" semantics, enforcing that, in case of failures, an API call either fails (does not get executed), or succeeds, but never gets executed more than once.

This seems to be (a) generally supported by most **grid** middleware, (b) implementable in distributed systems with reasonable effort, and (c) useful and intuitively expected by most end users. Any deviation from these semantics **MUST** be carefully documented by the implementation.

Beyond this, the SAGA API specification does *not* prescribe any consistency model for its operations, as we feel that this would be very hard to implement across different middleware platforms. A SAGA implementation **MAY** specify some consistency model, which **MUST** be documented. A SAGA implementation **SHOULD** always allow for application level consistency enforcement, for example by use of application level locks and mutexes.

2.9 Optimizing Implementations, Latency Hiding

Distributed applications are usually very sensitive to communication latencies. Several use cases in SAGA explicitly address this topic, and require the SAGA API to support (a) asynchronous operations, and (b) bulk operations, as both are commonly accepted latency hiding techniques. The SAGA task model (see Section 3.10) provides asynchronous operations for the SAGA API. Bulk operations have no explicit expression in SAGA. Instead, we think that implementations should be able to exploit the concurrency information available in the SAGA task model to transparently support bulk optimizations. In particular, the `saga::task_container` allows to run multiple asynchronous operations at the same time – implementations are encouraged to apply bulk optimizations in that situation. A proof-of-concept implementation in C++ demonstrates that bulk optimizations for task containers are indeed implementable, and perform very well [13]. We feel that this leaves the SAGA API simple, and at the same time allows for performance critical use cases.

Other optimizations are more explicit in the API, most notably the additional I/O operations for the `saga::file` class – those are described in more detail in Section 4.3.

Implementations are encouraged to exploit further optimizations; these **MUST NOT** change the semantics of the SAGA API though.

2.10 Configuration Management

The SAGA CORE WG spent a significant amount of discussion on deployment and configuration issues, and could not, as of yet, come to a complete agreement on these. More specifically we see the following problems related to the use of SAGA API implementations: Defining deployment and configuration related parts of an API normatively raises a number of issues, such as:

- As different SAGA **implementations** bind to different middleware, that middleware might need configuration information, such as the location of a GridRPC config file (see [19]), or the location of a service endpoint.
- If such configuration information **is** to be provided by the end user, the end user might face, eventually, a plethora of SAGA implementation *and middleware* specific configuration files, or environment variables, or other configuration mechanisms, which *would* break the SAGA abstraction from the middleware for the end user.
- Defining a SAGA configuration file format might succeed syntactically (e.g. ini file format), but must fail semantically, as it will be impossible to foresee on which middleware SAGA gets implemented, and to know which configuration information that middleware requires.

This leaves the dilemma that a configuration mechanism seems impossible to define generically, but by leaving it undefined, we break the abstraction SAGA is supposed to provide to the end user.

For the time being, *we leave* this problem *is left* to (a) the middleware developers, (b) to the SAGA implementors, and (c) to the SAGA deployment (i.e. system administrators). *We hope that* Experience gathered by these groups will *hopefully* allow *us* to revise this topic, and to define a generic, simple, *and* abstract approach to the configuration problem.

2.11 The 'URL Problem'

The end user might expect the SAGA API, as a high level and simple API, to handle protocol specific issues transparently. In particular, she might expect that SAGA gracefully and intelligently handles a URL such as

```
http://host.net/tmp/file
```

even if HTTP as *a* protocol is, in fact, not available at `host.net`, but for example the FTP protocol is.

However, this innocently looking problem has far reaching consequences, and in fact is, to the best of our knowledge, unresolved. Consider the following server setup on `host.net`:

```
FTP server root:    /var/ftp/pub/
HTTP server root:   /var/http/htdocs/
```

The entities described by the two URLs

```
http://host.net/tmp/file  
ftp://host.net/tmp/file
```

hence refer to different files on host.net! Even worse: it might be (and often is) impossible to access the HTTP file space via the FTP service, and vice versa.

Similar considerations hold *for absolute file names, and* for file names relative to the user's home directory. Consider:

```
http://host.net/~user/tmp/file
```

This URL may point to

```
file:///home/user/public_html/tmp/file
```

and not, as could have been expected, to

```
file:///home/user/tmp/file
```

Hence, a reliable translation of URLs between different protocols (*or protocol schemes*) is only possible, if the exact server setup of all affected protocol serving services is known. This knowledge is often not available.

Further, even if a correct translation of protocols and hence URLs succeeds, there is no guarantee that the referred file is actually available via this protocol, with the same permissions etc. – this again depends on the service configuration.

SAGA 'solution' to the 'URL Problem'

1. A SAGA compliant implementation MAY be able to transparently translate URLs, but is not required to do so. Further, this behaviour CAN vary during the runtime of the program.
2. *A SAGA compliant implementation MUST provide the **translate** method as part of the `saga:url` class. That method allows the end user to check if a specific URL translation can be performed.*
3. The SAGA API specification allows the use of the placeholder 'any' (as in `any://host.net/tmp/file`). A SAGA compliant implementation MAY be able to choose a suitable protocol automatically, but CAN decline the URL with an `IncorrectURL` exception.
4. Abstract name spaces, such as the name space used by replica systems, or by grid file systems, hide this problem efficiently and transparently from the end user. We encourage implementations to use such name spaces.
5. A URL which cannot be handled for the stated reasons MUST cause the exception `IncorrectURL` to be thrown. Note that this holds only for

those cases where a given URL cannot be handled *as such*, e.g. because the protocol is unsupported, `any://` cannot be handled, or a necessary URL translation failed. The detailed error message SHOULD give advice to the end user which protocols are supported, and which types of URL translations can or cannot be expected to work. *The `IncorrectURL` exception is thus listed on all methods which handle URLs as parameters, but is not individually motivated in the detailed method specifications.*

6. Any other error related to the URL (e.g. *file at service is not available* `invalid file name`) MUST be indicated by the exceptions as listed in the method specifications in this document (*in most cases a `BadParameter` exception is applicable.*

We are aware that this 'solution' is sub-optimal, but we also think that, if cleverly implemented with the help of information services, service level setup information, and global name spaces, this approach can simplify the use of the SAGA API significantly. We will carefully watch the work of related OGF groups, such as the global naming efforts in the Grid FileSystem Working Group (GFS-WG), and will revise this specification if any standard proposal is put forward to address the described problem.

Note that SAGA, unlike other Grid APIs such as the GAT[2], is fully adopting RFC 3986[5]: URLs which include a scheme can, according to that RFC, not express relative locations. The following two URLs are thus expected to point to the same location:

```
gridftp://remote.host.net/bin/date  
gridftp://remote.host.net//bin/date
```

2.12 Miscellaneous Issues

2.12.1 File Open Flags

For files, flags are used to specify if an `open` is truncating, creating, and/or appending to an existing entity. For jobs, and in particular for file staging, the LSF scheme is used (e.g. `'url >> local_file'` for appending a remote file to a local one after staging). We are aware of this seeming inconsistency. However, we think that a forceful unification of both schemes would be more awkward to use, and at the same time less useful.

2.12.2 Byte Ordering

Applications on grids as inherent homogeneous environments will often face different native byte orders on different resources. In general, SAGA always operates in the locally native byte ordering scheme, unless explicitly notified. The byte oriented I/O interfaces (files and streams) are naturally ignorant to the byte ordering. Finally, any byte order conversion on data exchange between two SAGA applications, e.g. by using files, streams or remote procedure calls, must be taken care of in application space, unless noted otherwise.

3 SAGA API Specification – Look & Feel

The SAGA API consists of a number of interface and class specifications. The relation between these is shown in Figure 2 on Page 35. This figure also marks which interfaces are *dominating part of* the SAGA **Look-&-Feel**, and which classes are combined into packages.

This and the next section form the normative part of the SAGA Core API specification. It has one subsection for each package, starting with those interfaces that define the SAGA **Look-&-Feel** (*top level interfaces first*), followed by the various, **capability-providing** packages: job management, name space management, file management, replica management, streams, and remote procedure call.

The SAGA **Look-&-Feel** is defined by a number of classes and interfaces which ensure the non-functional properties of the SAGA API (see [18] for a complete list of non-functional requirements). These interfaces and classes are intended to be used by the functional SAGA API packages, and are hence thought to be orthogonal to the functional scope of the SAGA API.

SAGA implementations should be able to implement the SAGA **Look-&-Feel** API packages independent of the grid middleware backend. *That is This*, however, *not guaranteed to be the case. might not always be possible, at least to a full extent*. In particular Monitoring and Steering, but also *Attributes and* asynchronous operations, may need explicit support from the backend system. As such, methods in these four packages **MUST** be expected to throw a **NotImplemented** exception, in accordance with the SAGA implementation compliance **guidelines** given in *Section 2.4*. *The NotImplemented exception is listed in the respective method description details, but, unlike other listed exceptions, not separately motivated*. Similarly, the **IncorrectURL** exception is listed when appropriate, but is not, in general, separately motivated or detailed – the semantic conventions for this exception are as defined in Section 2.11.

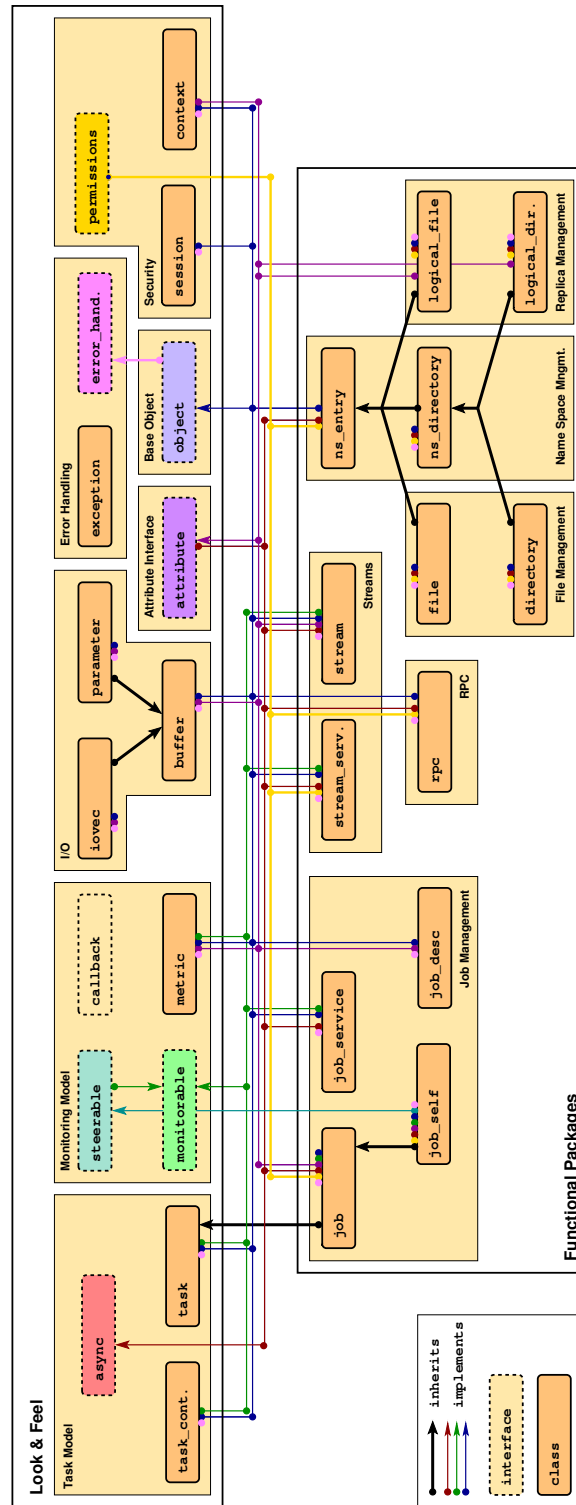

Figure 2: The SAGA class and interface hierarchy.

3.1 SAGA Error Handling

Each SAGA API call has an associated list of exceptions it may throw. These exceptions all extend the `saga::exception` class described below.

All objects in SAGA implement the `error_handler` *interface*, which allows a user of the API to query for the latest error associated with a **SAGA** object (*pull*). In languages with *exception facilities* *exception-handling mechanisms*, such as Java, C++ and Perl, the language binding MAY allow exceptions to be thrown. *If an exception handling mechanism is included in a language binding, the error_handler MUST NOT be included in the same binding.* Bindings for languages without exception handling capabilities MUST stick to the `error_handler` interface described here, but MAY define additional language-native means for error reporting.

For asynchronous operations, the error handler interface is provided by the task instance performing the operation, and not by the object which created the task.

If an error occurs during object creation, then the error handler interface of the session the object was to be created in will report the error.

For objects implementing the `error_handler` interface, each method invocation on that object resets any error caused by a previous method invocation on that object.

In languages bindings where this is appropriate, some API methods return POSIX `errno` codes for errors. This is *true the case* in particular for `read()`, `write()` and `seek()`, for `saga::file` and `saga::stream`. The respective method descriptions provide explicit details of how `errno` error codes are utilized. In any case, *whenever numerical the user* `errno` codes are *to be used as they are used in used, they have to be conforming to* POSIX.1 [21].

Any other details of the error handling mechanisms will be defined in the respective language bindings, if required.

3.1.1 Specification

```

package saga.error
{
    class exception
    {
!       CONSTRUCTOR          (in  object      obj,
+                               in  string      message,
+                               out exception    e);
+       CONSTRUCTOR          (in  string      message,
+                               out exception    e);
+       DESTRUCTOR           (void);

-       what                  (out string      message);
        get_message          (out string      message);
!       get_object           (out object      obj);
    }

+   class NotImplemented      : extends saga::exception { }
+   class IncorrectURL        : extends saga::exception { }
+   class BadParameter        : extends saga::exception { }
+   class AlreadyExists       : extends saga::exception { }
+   class DoesNotExist        : extends saga::exception { }
+   class IncorrectState      : extends saga::exception { }
+   class PermissionDenied    : extends saga::exception { }
+   class AuthorizationFailed  : extends saga::exception { }
+   class AuthenticationFailed : extends saga::exception { }
+   class Timeout             : extends saga::exception { }
+   class NoSuccess           : extends saga::exception { }

    interface error_handler
    {
        has_error              (out boolean      has_error);
        get_error              (out exception    error);
    }
}

```

3.1.2 Specification Details

SAGA provides a set of well-defined *exceptions (error states)* which MUST be supported by the implementation. As to whether these error states are critical, non-critical or fatal depends on, (a) the specific implementation (one implementation might be able to recover from an error while another implementation might not), and (b) the specific application use case (e.g. the error 'file does not exist' may or may not be fatal, depending on whether the application really needs information from that file).

Several In language bindings where this is appropriate, some SAGA methods do not raise exceptions on certain error conditions, but return an error code instead. For example, file.read() might return an error code indicating that a not enough data is available right now. The error codes used in SAGA are based on the definitions for errno as defined by POSIX, and MUST be used in a semantically identical manner.

This specification defines the set of allowed exceptions for each method explicitly – *that this set is normative The SAGA specification defines which exceptions can be thrown by which method. : other SAGA exceptions MUST NOT be thrown on these methods. Also, implementations MUST NOT specify or use other SAGA exceptions than listed in this specification.*

For example, a certain implementation might have authorization on session creation, and could throw an AuthorizationFailed exception on attempts to create a session – even though this is not specified in the SAGA specification. New SAGA exception types, however, SHOULD NOT be defined by the implementation.

Additionally, an implementation MAY throw other, non-SAGA exceptions, e.g. on system errors, resource shortage etc. SAGA implementations MUST, however, translate grid middleware-specific exceptions and error conditions into SAGA exceptions whenever possible, in order to avoid middleware specific exception handling on applications level – that would clearly contradict the intent of SAGA to be middleware independent.

In the SAGA language bindings, exceptions are either derived from the base SAGA exception types, or are error codes with that specific name etc. The exact rendering is language binding specific; for details, see the language bindings. Note that the detailed description for saga::exception below does not list the CONSTRUCTORS and DESTRUCTORS for all exception classes individually, but only for the base exception class. The individual exception classes MUST NOT add syntax or semantics to the base exception class.

The string returned by *what()* and `get_message()` MUST be formatted as follows:

```
"<ExceptionName>: message"
```

where `<ExceptionName>` MUST match the literal exception names as defined in this document, and `message` SHOULD be a detailed, human readable description of the cause of the exception.

For implementations with multiple middleware bindings, it can be difficult to provide detailed and conclusive error messaging with a single exception. To support such implementations, language bindings MAY allow nested exceptions. The outermost exception MUST, however, follow the syntax and semantics guidelines described above. Implementations of such bindings which only bind to a single backend MUST support the defined interface for nested exceptions as well, in order to keep the application independent of the specifics of the SAGA implementation, but will then in general not be able to return lower-level exceptions.

*The exceptions available in SAGA are listed below, with a number of explicit examples on when exceptions should be thrown. These examples are not normative, but merely illustrative. This list of exceptions is sorted, with the most specific exceptions *are* listed first and least specific last. The most specific exception possible (i.e. applicable) MUST be thrown on all error conditions. This means that if multiple exceptions are applicable to an error condition (e.g. `PermissionDenied` and `NoSuccess` for opening a file with incorrect permissions), then that exception MUST be thrown which gives more specific information about the respective error condition: e.g., `PermissionDenied` describes the error condition much more explicitly than a generic `NoSuccess`.*

- **NotImplemented**

If a method is specified in the SAGA API, but cannot be provided by a specific SAGA implementation, this exception MUST be thrown. *Object constructors can also throw that exception, if the respective object is not implemented by that SAGA implementation at all.* See also the notes about compliant implementations in *Section 2.4*.

Examples:

- An implementation based on Unicores might not be able to provide streams. The `saga::stream_server` constructor should throw a `NotImplemented` exception for *that such an* implementation.

The `IncorrectSession` exception was removed due to some implications of the new task model.

- **IncorrectURL**

This exception is thrown if a method is invoked with **a** URL argument that could not be handled. This error specifically indicates that an implementation **cannot**

handle the specified protocol, or *that* access to the specified entity via the given protocol is impossible. The exception MUST NOT be used to indicate any other error condition. See also the notes to 'The URL Problem' in [Section 2.11](#).

Examples:

- An implementation based on gridftp might be unable to handle http-based URLs sensibly, and might be unable to translate them into *gridftp* based URLs internally. The implementation should then throw an `IncorrectURL` exception if it encounters a http-based URL.
- *A URL is well formed, but includes characters or path elements which are not supported by the SAGA implementation or the backend. Then, an `IncorrectURL` exception is thrown, with detailed information on why the URL could not be used.*

- **BadParameter**

This exception indicates that at least one of the parameters of the method call is ill-formed, invalid, out of **bounds** or otherwise not usable. The error message MUST give specific information on what parameter caused the exception, and why.

Examples:

- a specified context type is not supported by the implementation
- a file name specified is invalid, e.g. too long, or contains characters which are not allowed
- an ivec for scattered read/write is invalid, e.g. has offsets which are out of **bounds**, or *refer to* non-allocated buffers
- a buffer to be written and the specified lengths are incompatible
- an enum specified is not known
- flags specified are incompatible (`ReadOnly` *and* `Truncate`)

- **AlreadyExists**

This exception indicates that an operation cannot succeed because an entity to be created or registered already exists or is already registered, and cannot be overwritten. Explicit flags on the method invocation may allow the operation to succeed, e.g. if they indicate that Overwrite is allowed.

Examples:

- a target for a file move already exists

- a file to be created already exists
- a name to be added to a logical file is already known
- a metric to be added to a object has the same name as an existing metric on that object

- **DoesNotExist**

This exception indicates that an operation cannot succeed because a required entity is missing. Explicit flags on the method invocation may allow the operation to succeed, e.g. if they indicate that Create is allowed.

Examples:

- a file to be moved does not exist
- a directory to be listed does not exist
- a name to be deleted is not in a replica set
- a metric asked for is not known to the object
- a context asked for is not known to the session
- a task asked for is not in a task container
- a job asked for is not known by the backend
- **an** attribute asked for is not supported

ReadOnly and WriteOnly exception are now part of the PermissionDenied exception, because of the changes to the SAGA permission model.

- **IncorrectState**

This exception indicates that the object a method was called on is in a state where that method cannot possibly succeed. A change of state might allow the method to succeed with the same set of parameters.

Examples:

- calling read on a stream which is not connected
- calling run on a task which was canceled
- calling resume on a job which is not suspended

- **PermissionDenied**

An operation failed because the **identity** used for the operation did not have

sufficient permissions to perform the operation successfully. The authentication and authorization steps have been completed successfully.

Examples:

- attempt to change or set a ReadOnly attribute
- attempt to change or update a ReadOnly metric
- calling write on a file which is opened for read only
- *calling read on a file which is opened for write only*
- although a user could login to a remote host via GridFTP and could be mapped to a local user, the write on /etc/passwd failed.

Examples:

- **AuthorizationFailed**

An operation failed because none of the available contexts of the used session could be used for successful **authorization**. That error indicates that the resource could not be accessed at all, and not that an operation was not available due to restricted permissions. The authentication step has been completed successfully.

The differences between AuthorizationFailed and PermissionDenied are, admittedly, subtle. Our intention for introducing both exceptions was to allow to distinguish between administrative authorization failures (**on** VO and DN level), and backend related authorization failures (which can often be resolved on user level).

The AuthorizationFailed exception SHOULD be thrown when the **backend** does not allow the execution of the requested operation at all, whereas the PermissionDenied exception SHOULD be thrown if the operation was executed, but failed due to insufficient privileges.

Examples:

- although a certificate was valid on a remote GridFTP server, the distinguished name could not be mapped to a valid local user id. A call to file.copy() should then throw an AuthorizationFailed exception.

- **AuthenticationFailed**

An operation failed because none of the available session contexts could successfully be used for authentication.

Examples:

- a remote host does not accept a X509 certificate because the respective CA is unknown there. A call to `file.copy()` should then throw an `AuthenticationFailed` exception.

- **Timeout**

This exception indicates that a remote operation did not complete successfully because the network communication or the remote service timed out. The time **waited before an implementation** raises a `Timeout` exception depends on implementation and backend details, and SHOULD be documented by the implementation. *That This exception MUST NOT be thrown if a timed `wait()` or similar method times out. - that is indicated by the method's return value, and does not pose an error condition. The latter is not an error condition and gets indicated by the method's return value.*

Examples:

- a remote file authorization request timed out
- a remote file read operation **timed** out
- a host name resolution timed out
- a started file transfer stalled and timed out
- **an asynchronous** file transfer stalled and timed out

- NoSuccess

This exception indicates that an operation failed semantically, e.g. the operation was not successfully performed. This exception is the least specific exception defined in SAGA, and CAN be used for all error conditions which do not indicate a more specific exception specified above. *The error message SHOULD always contain some further detail, describing the circumstances which caused the error condition.*

Examples:

- a once open file is not available right now
- a backend response cannot be parsed
- *a remote procedure call failed due to a corrupted parameter stack*
- a file copy was interrupted mid-stream, due to shortage of disk space

Class exception

This is the exception base class inherited by all exceptions thrown by a SAGA object implementation.

Note that `saga::exception` does not implement the `saga::object` interface.

```

- CONSTRUCTOR
  Purpose:  create the exception
!   Format:  CONSTRUCTOR  (in  object      obj,
+                        in  string      message
!   Inputs:  obj:         the object associated with the
                        exception.
+                        message:      the message to be associated
+                        with the new exception

```

```

+   InOuts:  -
+   Outputs: e:           the newly created exception
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   -
+   Notes:    -

+
+ - CONSTRUCTOR
+   Purpose:  create the exception, without associating
+             a saga object instance
+   Format:   CONSTRUCTOR (in string      message
+                         out exception   e);
+   Inputs:   message:    the message to be associated
+                         with the new exception
+   InOuts:   -
+   Outputs:  e:           the newly created exception
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   -
+   Notes:    -
+
+   - DESTRUCTOR
+     Purpose: destroy the exception
+     Format:   DESTRUCTOR (in exception e);
+     Inputs:   e:         the exception to destroy
+   !
+   InOuts:    -
+   Outputs:   -
+   PreCond:   -
+   PostCond:  -
+   Perms:     -
+   Throws:    -
+   Notes:     -

-
- - what
-   what is an alias for get_message.
-

- get_message
! Purpose: gets the message associated with the exception
Format:   get_message (out string message);
Inputs:   -

```

```

+   InOuts:  -
!   Outputs: message:      the error message
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   -
+   Notes:    - the returned string MUST be formatted as
!               described earlier in this section.

- get_object
  Purpose: gets the SAGA object associated with exception
!   Format: get_object      (out object obj);
+   Inputs:  -
+   InOuts:  -
!   Outputs: obj:           the object associated with the
+                           exception
+   PreCond: - an object was associated with the exception
+               during construction.
+   PostCond: -
+   Perms:    -
!   Throws:   DoesNotExist
+               NoSuccess
+   Notes:    - the returned object is a shallow copy of the
+               object which was used to call the method which
+               caused the exception.
!               - if the exception is raised in a task, e.g. on
+               task.rethrow(), the object is the one which the
+               task was created from. That allows the
+               application to handle the error condition
+               without the need to always keep track of
+               object/task relationships.
+               - an 'DoesNotExist' exception is thrown when no
+               object is associated with the exception, e.g.
!               if an 'NotImplemented' exception was raised
+               during the construction of an object.

```

Interface error handler

*The **error_handler** interface allows the application to retrieve exceptions. An alternative approach would be to return an error code for all method invocations. This, however, would put a significant burden on languages with exception handling, and would also complicate the management of return values. Language*

bindings for languages with exception support will thus generally not implement the `error_handler` interface, but use exceptions instead.

*Implementations which are using the interface maintain an internal error state for each class instance providing the interface. That error state is **false** by default, and is set to **true** whenever an method invocation meets an error condition which would, according to this specification, result in an exception to be thrown.*

*The error state of an object instance can be tested with **has_error()**, and the respective exception can be retrieved with **get_error()**. Any one of these calls clears the error state (i.e. resets it to **false**). Note that there is no other mechanism to clear an error state – that means in particular that any successful method invocation on the object leaves the error state unchanged. If two or more subsequent operations on an object instance fail, then only the last exception is returned on **get_error()**. That mechanism allows to execute a number of calls, and to check if they resulted in any error condition, somewhat similar to **try/catch** statements in languages with exception support. However, it must be noted that an exception does not cause subsequent methods to fail, and does not inhibit their execution.*

*If **get_error()** is called on an instance whose error state is **false**, an **IncorrectState** exception is returned, which **MUST** state explicitly that the **get_error()** method has been invoked on an object instance which did not encounter an error condition.*

```

+   - has_error
+     Purpose:  tests if an object method caused an exception
+     Format:   has_error      (out bool      has_error);
+     Inputs:   -
+     InOuts:   -
+     Outputs:  has_error:      indicates that an exception was
+                               caught.
+     PreCond:  -
+     PostCond: - the internal error state is false.
+     Perms:    -
+     Throws:   -
+     Notes:    -
+
+   - get_error
+     Purpose:  retrieve an exception caught during a member
+               method invocation.
+     Format:   get_error      (out exception e);
+     Inputs:   -
+     InOuts:   -
+     Outputs:  e:              the caught exception

```

```

+   PreCond: - the internal error state is true.
+   PostCond: - the internal error state is false.
+   Perms: -
+   Throws: NotImplemented
+           IncorrectURL
+           BadParameter
+           AlreadyExists
+           DoesNotExist
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes: - the method throws the error/exception it is
+           reporting about.
+           - an 'IncorrectState' exception is also thrown
+           if the internal error state is false.

```

3.1.3 Examples

Code Example

```

1  ///////////////////////////////////////////////////////////////////

10 //
11 int main ()
12 {
13     try
14     {
15         saga::file f ("file://localhost/etc/passwd");
16         f.copy ("file:///usr/tmp/passwd.bak");
17     }
18
19     catch ( const saga::exception::PermissionDenied & e )
20     {
21         std::cerr << "SAGA error: No Permissions!" << std::endl;
22         return (-1);

```

```
23     }
24
25     catch ( const saga::exception & e )
26     {
27         std::cerr << "SAGA error: "
28                 << e.get_message ()
29                 << std::endl;
30         return (-1);
31     }
32
33     return (0);
34 }
35
36
37 ///////////////////////////////////////////////////////////////////
38 //
39 // exception handling for tasks
40 //
41 int main ()
42 {
43
44     saga::file f ("file://localhost/etc/passwd");
45
46     saga::task t = f.copy <saga::task::Async>
47                     ("file:///usr/tmp/passwd.bak");
48
49     t.wait ();
50
51     if ( t.get_state () == saga::task::Failed )
52     {
53         try {
54             task.rethrow ();
55         }
56         catch ( const saga::exception & e )
57         {
58             std::cout << "task failed: "
59                     << e.get_message ()
60                     << std::endl;
61         }
62         return (-1);
63     }
64     return (0);
65 }
```

3.2 SAGA Base Object

The SAGA object interface provides methods which are essential for all SAGA objects. It provides a unique ID which helps maintain a list of SAGA objects at the application level as well as allowing for inspection of objects type and its associated session.

The object id MUST be formatted as UUID, as standardized by the Open Software Foundation (OSF) as part of the Distributed Computing Environment (DCE). The UUID format is also described in the IETF RFC-4122 [16].

Note that there are no object IDs for the various SAGA exceptions, but only one ID for the `saga::exception` base class. Also, it is not possible to inspect a SAGA object instance for the availability of certain SAGA interfaces, as they are fixed and well defined by the SAGA specification. Language bindings MAY, however, add such inspection, if that is natively supported by the language.

3.2.1 Specification

```

package saga.object
{
    enum object_type
    {
-       Unknown          = -1,
        Exception         =  1,
+       URL              =  2,
+       Buffer           =  3,
        Session          =  4,
        Context          =  5,
        Task             =  6,
        TaskContainer    =  7,
!       Metric          =  8,
!       NSEntry         =  9,
!       NSDirectory     = 10,
+       IOVec           = 11,
!       File            = 12,
!       Directory       = 13,
!       LogicalFile     = 14,
!       LogicalDirectory = 15,
!       JobDescription  = 16,
!       JobService      = 17,
!       Job             = 18,
!       JobSelf         = 19,
    }
}

```

```

!      StreamService      = 20,
!      Stream             = 21,
+      Parameter          = 22,
+      RPC                 = 23,
-      Multiplexer        = 24
    }

    interface object : implements saga::error-handler
    {
        get_id      (out string      id      );
        get_type     (out object_type type );
!      get_session  (out session     s      );

        // deep copy
        clone        (out object      clone  );
    }
}

```

3.2.2 Specification Details

Enum object_type

*The SAGA **object_type** enum allows for inspection of SAGA object instances. This, in turn, allows to treat large numbers of SAGA object instances in containers, without the need to create separate container types for each specific SAGA object type. Bindings to languages that natively support inspection on object types MAY omit this enum and the **get_type()** method.*

*SAGA extensions which introduce new SAGA objects (i.e. introduce new classes which implement the **saga::object** interface) MUST define the appropriate **object_type** enums for inspection. SAGA implementations SHOULD support these enums for all packages which are provided in that implementation, even for classes which are not implemented.*

Interface object

```

- get_id
  Purpose:  query the object ID
  Format:   get_id          (out string id);

```

```

        Inputs:  -
+       InOuts:  -
!       Outputs: id:                uuid for the object
+       PreCond:  -
+       PostCond: -
+       Perms:    -
+       Throws:   -
+       Notes:    -

- get_type
  Purpose: query the object type
  Format:  get_type                (out object_type type);
  Inputs:  -
+  InOuts:  -
!  Outputs: type:                  type of the object
+  PreCond:  -
+  PostCond: -
+  Perms:    -
+  Throws:   -
+  Notes:    -

- get_session
  Purpose: query the objects session
  Format:  get_session            (out session s);
  Inputs:  -
+  InOuts:  -
!  Outputs: s:                    session of the object
+  PreCond: - the object was created in a session, either
+            explicitly or implicitly.
+  PostCond: - the returned session is shallow copied.
+  Perms:    -
!  Throws:   DoesNotExist
  Notes:    - if no specific session was attached to the
              object at creation time, the default SAGA
              session is returned.
!           - some objects do not have sessions attached,
              such as job_description, task, metric, and the
              session object itself. For such objects, the
!           method raises a 'DoesNotExist' exception.

// deep copy:
-----

```

```

- clone
  Purpose: deep copy the object
  Format:  clone                      (out object clone);
  Inputs:  -
+  InOuts: -
!  Outputs: clone:                    the deep copied object
+  PreCond: -
+  PostCond: - apart from session and callbacks, no other
               state is shared between the original object
               and it's copy.
+  Perms:    -
+  Throws:   NoSuccess
  Notes:    - that method is overloaded by all classes
               which implement saga::object, and returns
               a deep copy of the respective class type
               (the method is only listed here).
!           - the method SHOULD NOT cause any backend
               activity, but is supposed to clone the client
               side state only.
!           - for deep copy semantics, see Section 2.

```

3.2.3 Examples

Code Example

```

1  // c++ example
2
3  // have 2 objects, streams and files, and do:
4  // - read 100 bytes
5  // - skip 100 bytes
6  // - read 100 bytes
7
8  int out;
9  char data1[100];
10 char data2[100];
11 char data[100];
12
13 saga::buffer buf1 (data1, 100);
14 saga::buffer buf2 (data2, 100);
15 saga::buffer buf;
16
17 // create objects
18 saga::file f (url[1]);
19 saga::stream s (url[2]);
20
21 // f is opened at creation, s needs to be connected

```

```
22 s.connect ();
23
24 // create tasks for reading first 100 bytes ...
25 saga::task t1 = f.read <saga::task> (100, buf1);
26 saga::task t2 = s.read <saga::task> (100, buf2);
27
28 // create and fill the task container ...
29 saga::task_container tc;
30
31 tc.add (t1);
32 tc.add (t2);
33
34 // ... and wait who gets done first
35 while ( saga::task t = tc.wait (saga::task::Any) )
36 {
37     // depending on type, skip 100 bytes then create a
38     // new task for the next read, and re-add to the tc
39
40     switch ( t.get_object().get_type () )
41     {
42     case saga::object::File :
43         // point buf to results
44         buf = buf1;
45
46         // get back file object
47         saga::file f = saga::file (t.get_object ());
48
49         // skip for file type (sync seek)
50         saga::file (f.seek (100, SEEK_SET);
51
52         // create a new read task
53         saga::task t2 = f.read <saga::task> (100, buf1));
54
55         // add the task to the container again
56         tc.add (t2);
57
58         break;
59
60     case saga::object::Stream :
61         // point buf to results
62         buf = buf2;
63
64         // get back stream object
65         saga::stream s = saga::stream (t.get_object ());
66
67         // skip for stream type (sync read and ignore)
68         saga::stream (s.read (100, buf2);
69
70         // create a new read task
71         saga::task t2 = s.read <saga::task> (100, buf2));
```

```
72         // add the task to the container again
73         tc.add (t2);
74
75         break;
76
77     default:
78         throw exception ("Something is terribly wrong!");
79     }
80
81     std::cout << "found: '" << out << " bytes: "
82               << buf.get_data ()
83               << std::endl;
84
85     // tc is filled again, we run forever, read/seeking from
86     // whatever we find after the wait.
87 }
88
```

3.3 SAGA URL Class

This whole section has been added to the specification!

In many places in the SAGA API, URLs are used to reference remote entities. In order to

- simplify the construction and the parsing of URLs on application level,
- allow for sanity checks within and outside the SAGA implementation,
- simplify and unify the signatures of SAGA calls which accept URLs,

a SAGA URL class is used. This class provides means to set and access the various elements of a URL. The class parses the URL in conformance to RFC-3986 [5].

In respect to the URL problem (stated in Section 2.11), the class provides the method `translate` (in `string scheme`), which allows to translate a URL from one scheme to another – with all the limitations mentioned in Section 2.11.

```
package saga.url
{
  class url : implements  saga::object
                  // from object  saga::error_handler
  {
    CONSTRUCTOR    (in  string    url      ,
                    out buffer    obj      );
    DESTRUCTOR     (in  buffer    obj      );

    set_string     (in  string    url      = "");
    get_string     (out string    url      );

    set_scheme     (in  string    scheme   = "");
    get_scheme     (out string    scheme   );

    set_host       (in  string    host     = "");
    get_host       (out string    host     );

    set_port       (in  int       port     = "");
    get_port       (out int       port     );
```

```

        set_fragment (in string fragment = "");
        get_fragment (out string fragment );

        set_path      (in string path      = "");
        get_path      (out string path      );

        set_query      (in string query      = "");
        get_query      (out string query      );

        set_userinfo   (in string userinfo = "");
        get_userinfo   (out string userinfo );

        translate      (in string scheme    ,
                        out url    url      );
    }
}

```

3.3.1 Specification Details

Class url

```

- CONSTRUCTOR
  Purpose:  create a url instance
  Format:   CONSTRUCTOR      (in string url = "",
                              out url    obj);
  Inputs:   url:              initial URL to be used
  InOuts:   -
  Outputs:  url:              the newly created url
  PreCond:  -
  PostCond: -
  Perms:    -
  Throws:   NotImplemented
            BadParameter
+          NoSuccess
  Notes:    - if the implementation cannot parse the given
              url, a 'BadParameter' exception is thrown.
            - this constructor will never throw an
              'IncorrectURL' exception, as the
              interpretation of the URL is not part of this
              class's functionality.
            - the implementation MAY change the given

```

URL as long as that does not change the resource the URL is pointing to. For example, an implementation may normalize the path element of the URL.

- DESTRUCTOR

Purpose: destroy a url

Format: DESTRUCTOR (in url obj);

Inputs: obj: the url to destroy

InOuts: -

Outputs: -

PreCond: -

PostCond: -

Perms: -

Throws: -

Notes: -

- set_string

Purpose: set a new url

Format: set_string (in string url = "");

Inputs: url: new url

InOuts: -

Outputs: -

PreCond: -

PostCond: -

Perms: -

Throws: NotImplemented
BadParameter

Notes: - the method is semantically equivalent to
destroying the url, and re-creating it with
the given parameter.
- the notes for the DESTRUCTOR and the
CONSTRUCTOR apply.

- get_string

Purpose: retrieve the url as string

Format: get_string (out string url);

Inputs: -

InOuts: -

Outputs: url: string representing the url

PreCond: -

PostCond: -

Perms: -

Throws: NotImplemented

Notes: - the URL may be empty, e.g. after creating the instance with an empty url parameter.

- set_*

Purpose: set an url element

```
Format:  set_<element>      (in  string <element> = "");
         set_scheme        (in  string scheme   = "");
         set_host          (in  string host     = "");
         set_port          (in  int   port      = "");
         set_fragment      (in  string fragment = "");
         set_path          (in  string path     = "");
         set_query         (in  string query    = "");
         set_userinfo      (in  string userinfo = "");
```

Inputs: <element>: new url <element>

InOuts: -

Outputs: -

PreCond: -

PostCond: - the <element> part of the URL is updated.

Perms: -

Throws: NotImplemented

BadParameter

Notes: - these calls allow to update the various elements of the url.
 - the given <element> is parsed, and if it is either not well formed (see RFC-3986), or the implementation cannot handle it, a 'BadParameter' exception is thrown.
 - if the given <element> is empty, it is removed from the URL. If that results in an invalid URL, a 'BadParameter' exception is thrown.
 - the implementation MAY change the given elements as long as that does not change the resource the URL is pointing to. For example, an implementation may normalize the path element.

- get_*

Purpose: get an url element

```
Format:  get_<element>      (out string <element>);
         get_scheme        (out string scheme );
         get_host          (out string host   );
         get_port          (out int   port    );
         get_fragment      (out string fragment );
```

```

        get_path          (out string path    );
        get_query         (out string query   );
        get_userinfo      (out string userinfo);

Inputs:  -
InOuts:  -
Outputs: <element>:      the url <element>
PreCond: -
PostCond: -
Perms:   -
Throws:  NotImplemented
Notes:   - these calls allow to retrieve the various
          elements of the url.
          - the returned <element> is either empty, or
            guaranteed to be well formed (see RFC-3986).

- translate
Purpose: translate an URL to a new scheme
Format:  translate        (in  string scheme,
                           out url   url);

Inputs:  scheme:          the new scheme to
                           translate into

InOuts:   -
Outputs:  url:            string representation of
                           the translated url

PreCond:  -
PostCond: -
Perms:    -
Throws:   NotImplemented
          BadParameter
          NoSuccess
Notes:    - the notes from section 'The URL Problem' apply.
          - if the scheme is not supported, a
            'BadParameter' exception is thrown.
          - if the scheme is supported, but the url
            cannot be translated to the scheme, a
            'NoSuccess' exception is thrown.
          - if the url can be translated, but cannot be
            handled with the new scheme anymore, no
            exception is thrown. That can only be
            detected if the returned string is again used
            in a URL constructor, or with set_string().
          - the call does not change the URL represented
            by the class instance itself, but the
            translation is only reflected by the returned
            url string.

```

3.3.2 Examples

Code Example

```

1  // C++ URL examples
2
3  int main (int argc, char ** argv)
4  {
5      if ( argc < 1 )
6          return -1;
7
8      std::string url_string = argv[1];
9
10     try
11     {
12         saga::url url (url_string);
13
14         cout << "url      : " << url.get_string    () << endl;
15         cout << "===== " << endl;
16         cout << "scheme   : " << url.get_scheme    () << endl;
17         cout << "host     : " << url.get_host      () << endl;
18         cout << "port     : " << url.get_port      () << endl;
19         cout << "fragment : " << url.get_fragment  () << endl;
20         cout << "path     : " << url.get_path      () << endl;
21         cout << "query    : " << url.get_query     () << endl;
22         cout << "userinfo : " << url.get_userinfo  () << endl;
23         cout << "===== " << endl;
24
25         url.set_scheme   ("ftp");
26         url.set_host     ("ftp.remote.net");
27         url.set_port     (1234);
28         url.set_fragment ("");
29         url.set_path     ("/tmp/data");
30         url.set_query    ("");
31         url.set_userinfo ("ftp:anon");
32
33         cout << "===== " << endl;
34         cout << "scheme   : " << url.get_scheme    () << endl;
35         cout << "host     : " << url.get_host      () << endl;
36         cout << "port     : " << url.get_port      () << endl;
37         cout << "fragment : " << url.get_fragment  () << endl;
38         cout << "path     : " << url.get_path      () << endl;
39         cout << "query    : " << url.get_query     () << endl;
40         cout << "userinfo : " << url.get_userinfo  () << endl;
41         cout << "===== " << endl;
42         cout << "url      : " << url.get_string    () << endl;
43     }

```

44

}

3.4 SAGA I/O Buffer

This whole section has been added to the specification!

The SAGA API includes a number of calls which perform byte-level I/O operations, e.g. `read()`/`write()` on files and streams, and `call()` on rpc instances. Future SAGA API extensions are expected to increase the number of I/O methods. The `saga::buffer` class encapsulates a sequence of bytes to be used for such I/O operations – that allows for uniform I/O syntax and semantics over the various SAGA API packages.

The class is designed to be a simple container containing one single element (the opaque data). The data can either be allocated and maintained in application memory, or can be allocated and maintained by the SAGA implementation. The latter is the default, and applies when no data and no size are specified on buffer construction.

For example, an application that has data memory already allocated and filled, can create and use a buffer by calling

```
// create buffer with application memory
char data[1000];
saga::buffer b (data, 1000);
```

The same also works when used with the respective I/O operations:

```
// write to a file using a buffer with application memory
char data[1000] = ...;
file.write (saga::buffer (data, 1000));
```

Another application, which wants to leave the buffer memory management to the SAGA implementation, can use a second constructor, which causes the implementation to allocate memory on the fly:

```
// create empty, implementation managed buffer
saga::buffer b; // no data nor size given!

// read 100 byte from file into buffer
file.read (b, 100);

// get memory from SAGA
const char * data = b.get_data ();

// or use data directly
std::cout << "found: " << b.get_data () << std::endl;
```

Finally, an application can leave memory management to the implementation, as above, but can specify how much memory should be allocated by the SAGA implementation:

```
// create an implementation managed buffer of 100 byte
saga::buffer b (100);

// get memory from SAGA
const char * data = b.get_data ();

// fill the buffer
memcpy (data, source, b.get_size ());

// use data for write
file.write (b);
```

Application-managed memory **MUST NOT** be re- or de-allocated by the SAGA implementation, and implementation-managed memory **MUST NOT** be re- or de-allocated by the application. However, an application **CAN** change the *content* of implementation managed memory, and vice versa.

Also, a buffer's contents **MUST NOT** be changed by the application while it is in use, i.e. while any I/O operation on that buffer is ongoing. For asynchronous operations, an I/O operation is considered ongoing if the associated `saga::task` instance is not in a final state.

If a buffer is too small (i.e. more data are available for a read, or more data are required for a write), only the available data are used, and an error is returned appropriately. If a buffer is too large (i.e. read is not able to fill the buffer completely, or write does not need the complete buffer), the remainder of the buffer data **MUST** be silently ignored (i.e. not changed, and not set to zero). The error reporting mechanisms as listed for the specific I/O methods apply.

Implementation-managed memory is released when the buffer is destroyed, (either explicitly by calling `close()`, or implicitly by going out of scope). It **MAY** be re-allocated, and reset to zero, if the application calls `set_size()`.

Application-managed memory is released by the application. In order to simplify memory management, language bindings (in particular for non-garbage-collecting languages) **MAY** allow to register a callback on buffer creation which is called on buffer destruction, and which can be used to de-allocate the buffer memory in a timely manner. The `saga::callback` class **SHOULD** be used for that callback – those language bindings **SHOULD** thus define the buffer to be **monitorable**, i.e. it should implement the `saga::monitorable` interface. After the callback's invocation, the buffer **MUST NOT** be used by the implementation anymore.

When calling `set_data()` for application-managed buffers, the implementa-

tion MAY copy the data internally, or MAY use the given data pointer as is. The application SHOULD thus not change the data while an I/O operation is in progress, and only consider the data pointer to be unused after another `set_data()` has been called, or the buffer instance was destroyed.

Note that these conventions on memory management allow for zero-copy SAGA implementations, and also allow to reuse buffer instances for multiple I/O operations, which makes, for example, the implementation of pipes and filters very simple.

The buffer class is designed to be inherited by application-level I/O buffers, which may, for example, add custom data getter and setter methods (e.g. `set_jpeg()` and `get_jpeg()`). Such derived buffer classes can thus add both data formats and data models transparently on top of SAGA I/O. For developers who program applications for a specific community it seems advisable to standardize both data format and data model, and possibly to standardize derived SAGA buffers – that work is, at the moment, out of scope for SAGA. The SAGA API MAY, however, specify such derived buffer classes in later versions, or in future extensions of the API.

A buffer does not belong to a session, and a buffer object instance can thus be used in multiple sessions, for I/O operations on different SAGA objects.

Note that even if a buffer size is given, the `len_in` parameter to the SAGA I/O operations supersedes the buffer size. If the buffer is too small, a `'BadParameter'` exception will be thrown on these operations. If `len_in` is omitted and the buffer size is not known, a `'BadParameter'` exception is also thrown.

Note also that the `len_out` parameter of the SAGA I/O operations has not necessarily the same value as the buffer size, obtained with `buffer.get_size()`. A read may read only a part of the requested data, and a write may have written only a part of the buffer. That is not an error, as is described in the notes for the respective I/O operations.

SAGA language bindings may want to define a `const`-version of the buffer, in order to allow for safe implementations. A non-`const` buffer SHOULD then inherit the `const` buffer class, and add the appropriate constructor and setter methods. The same holds for SAGA classes which inherit from the `buffer`.

Also, language bindings MAY allow buffer constructors with optional `size` parameter, if the size of the given data is implicitly known. For example, the C++ bindings MAY allow an buffer constructor `buffer (std::string s)`. The same holds for SAGA classes that inherit from the `buffer`.

3.4.1 Specification

```

package saga.buffer
{
    class buffer : implements    saga::object
                        // from object saga::error_handler
    {
        CONSTRUCTOR (in  array<byte>  data,
                      in  int          size,
                      out buffer      obj);
        CONSTRUCTOR (in  int          size = -1,
                      out buffer      obj);
        DESTRUCTOR  (in  buffer      obj);

        set_size    (in  int          size = -1)
        get_size    (out int          size);

        set_data    (in  array<byte>  data,
                      in  int          size);
        get_data    (out array<byte>  data);

        close      (in  float          timeout = -0.0);
    }
}

```

3.4.2 Specification Details

Class buffer

```

- CONSTRUCTOR
  Purpose:  create an I/O buffer
  Format:   CONSTRUCTOR          (in  array<byte>  data,
                                  in  int          size,
                                  out buffer      obj);

  Inputs:   data:                data to be used
            size:                size of data to be used
  InOuts:   -
  Outputs:  buffer:              the newly created buffer
  PreCond:  - size >= 0
  PostCond: - the buffer memory is managed by the

```

```

        application.
    Perms:  -
    Throws: NotImplemented
           BadParameter
+         NoSuccess
    Notes:  - see notes about memory management.
           - if the implementation cannot handle the
             given data pointer or the given size, a
             'BadParameter' exception is thrown.
           - later method descriptions refer to this
             CONSTRUCTOR as 'first CONSTRUCTOR'.

- CONSTRUCTOR
  Purpose: create an I/O buffer
  Format:  CONSTRUCTOR          (in int          size = -1,
                                out buffer      obj);
  Inputs:  size:                size of data buffer
  InOuts:  -
  Outputs: buffer:              the newly created buffer
  PreCond: -
  PostCond: - the buffer memory is managed by the
               implementation.
               - if size > 0, the buffer memory is allocated by
                 the implmentation.
  Perms:  -
  Throws: NotImplemented
           BadParameter
+         NoSuccess
  Notes:  - see notes about memory management.
           - if the implementation cannot handle the
             given size, a 'BadParameter' exception is
             thrown.
           - later method descriptions refer to this
             CONSTRUCTOR as 'second CONSTRUCTOR'.

- DESTRUCTOR
  Purpose: destroy a buffer
  Format:  DESTRUCTOR          (in buffer obj);
  Inputs:  obj:                the buffer to destroy
  InOuts:  -
  Outputs: -
  PreCond: -
  PostCond: -
  Perms:  -

```

```
!   Throws:  -
!   Notes:   - if the instance was not closed before, the
!             DESTRUCTOR performs a close() on the instance,
!             and all notes to close() apply.

- set_data
  Purpose:   set new buffer data
  Format:    set_data          (in array<byte> data,
                               in int          size);
  Inputs:    data:             data to be used in buffer
             size:             size of given data
  InOuts:    -
  Outputs:    -
  PreCond:    -
  PostCond:  - the buffer memory is managed by the
               application.
  Perms:      -
  Throws:     NotImplemented
             BadParameter
             IncorrectState
  Notes:      - the method is semantically equivalent to
               destroying the buffer, and re-creating it with
               the first CONSTRUCTOR with the given size.
               - the notes for the DESTRUCTOR and the first
                 CONSTRUCTOR apply.

- get_data
  Purpose:    retrieve the buffer data
  Format:     get_data          (out array<byte> data);
  Inputs:     -
  InOuts:     -
  Outputs:    data:             buffer data to retrieve
  PreCond:    -
  PostCond:    -
  Perms:      -
  Throws:     NotImplemented
             DoesNotExist
             IncorrectState
  Notes:      - see notes about memory management
               - if the buffer was created as implementation
                 managed (size = -1), but no I/O operation has
                 yet been successfully performed on the buffer,
                 a 'DoesNotExist' exception is thrown.
```

```
- set_size
  Purpose: set size of buffer
  Format:  set_size      (in int    size = -1);
  Inputs:  size:         value for size
  InOuts:  -
  Outputs: -
  PreCond: -
  PostCond: - the buffer memory is managed by the
               implementation.
  Perms:    -
  Throws:   NotImplemented
            BadParameter
            IncorrectState
  Notes:    - the method is semantically equivalent to
               destroying the buffer, and re-creating it with
               the second CONSTRUCTOR using the given size.
            - the notes for the DESTRUCTOR and the second
              CONSTRUCTOR apply.

- get_size
  Purpose: retrieve the current value for size
  Format:  get_size      (out int    size);
  Inputs:  -
  InOuts:  -
  Outputs: size          value of size
  PreCond: -
  PostCond: -
  Perms:    -
  Throws:   NotImplemented
            IncorrectState
  Notes:    - if the buffer was created with negative size
               with the second CONSTRUCTOR, or the size was
               set to a negative value with set_size(), this
               method returns '-1' if the buffer was not yet
               used for an I/O operation.
            - if the buffer was used for a successfull I/O
               operation where data have been read into the
               buffer, the call returns the size of the
               memory which has been allocated by the
               implementation during that read operation.

- close
  Purpose: closes the object
```

```

Format:   close                (in float timeout = 0.0);
Inputs:   timeout              seconds to wait
InOuts:   -
Outputs:  -
Perms:    -
- PreCond: - the object was not closed before
+ PreCond: -
PostCond: - any operation on the object other than
!           close() or the DESTRUCTOR will cause
!           an 'IncorrectState' exception.
Throws:   NotImplemented
-         IncorrectState
Notes:    - it is assumed that a session which opened the
-           instance can also close it - otherwise the
-           backend entity must have changed its state,
-           which causes an 'IncorrectState' exception.
+ Notes:  - any subsequent method call on the object
+           MUST raise an 'IncorrectState' exception
+           (apart from DESTRUCTOR and close()).
-           - if the current data memory is managed by the
-             implementation, it is freed.
-           - close() can be called multiple times, with no
-             side effects.
-           - if the current data memory is managed by the
-             application, it is not accessed anymore by the
-             implementation after this method returns.
+           - if close() is implicitly called in the
+           DESTRUCTOR, it will never throw an exception.
-           - for resource deallocation semantics, see
-             Section 2.
-           - for timeout semantics, see Section 2.

```

3.4.3 Examples

Code Example

```

1  //////////////////////////////////////
2  // C++ I/O buffer examples
3  //////////////////////////////////////
4
5  //////////////////////////////////////
6  //
7  // general examples
8  //
9  // all following examples ignore the ssize_t return value, which

```

```
10 // should be the number of bytes successfully read
11 //
12 ///////////////////////////////////////////////////////////////////
13 {
14     char data[x][y][z];
15     char* target = data + 200;
16     buffer b;
17
18     // the following four block do exactly the same, reading
19     // 100 byte (the read parameter supersedes the buffer size)
20
21     // apps managed memory
22     {
23         b.set_data (target);
24         stream.read (b, 100);
25         printf ("%100s", target);
26     }
27
28     {
29         b.set_data (target, 100);
30         stream.read (b);
31         printf ("%100s", target);
32     }
33
34     {
35         b.set_data (target, 100);
36         stream.read (b, 100);
37         printf ("%100s", target);
38     }
39
40     {
41         b.set_data (target, 200);
42         stream.read (b, 100);
43         printf ("%100s", target);
44     }
45
46
47     // now for impl managed memory
48     {
49         b.set_size (100);
50         stream.read (b);
51         printf ("%100s", b.get_data ());
52     }
53
54     {
55         b.set_size (-1);
56         stream.read (b, 100);
57         printf ("%100s", b.get_data ());
58     }
59 }
```

```
60     {
61         b.set_size (200);
62         stream.read (b, 100);
63         printf ("%100s", b.get_data ());
64     }
65
66
67     // these two MUST throw, even if there is
68     // enough memory available
69
70     // app managed memory
71     {
72         b.set_data (target, 100);
73         stream.read (b, 200);
74     }

357     // data must be larger than offset + 300, otherwise bang!
358 }
359
```

```
360
361
362 ///////////////////////////////////////////////////////////////////
363 //
364 // the next two examples perform the same reads,
365 // but switch memory management in between
366 //
367 ///////////////////////////////////////////////////////////////////
368
369 // impl managed memory, then apps managed memory
370 {
371     {
372         char [x][y][z] data;
373         char* target = data + 200;
374
375         buffer b (100);
376
377         // impl managed
378         memcpy (b.get_data (), target, 100);
379         stream.write (b, 100);
380
381         b.set_data (target + 100, 200); // apps managed now
382                                         // impl data are gone after this
383
384         // apps managed
385         stream.write (b);
386
387     } // b dies here, apps data are ok after that, impl data are gone
388 }
389
390
391 // apps managed memory, then impl managed
392 {
393     {
394         char [x][y][z] data;
395         char* target = data + 200;
396
397         buffer b (target);
398
399         // apps managed
400         stream.write (b, 100);
401
402         b.set_size (200); // impl managed now
403         memcpy (b.get_data (), target + 100, 200);
404
405         // impl managed
406         stream.write (b);
407
408     } // b dies here, apps data are ok after that, impl data are gone
```

409

}

3.5 SAGA Session Management

The session object provides the functionality of a session, *handle*, which isolates independent sets of SAGA objects from each other. Sessions also support the management of security information (see `saga::context` in Section 3.6).

3.5.1 Specification

```

package saga.session
{
    class session : implements    saga::object
                        // from object    saga::error_handler
    {
        CONSTRUCTOR      (in  bool          default = true,
                          out session      obj);
        DESTRUCTOR        (in  session      obj);

        add_context       (in  context      context);
        remove_context    (in  context      context);
        list_contexts     (out array<context,1> contexts);
    }
}

```

3.5.2 Specification Details

Class session

Almost all SAGA objects are created in a SAGA session, and are associated with this (and only this) session for their whole life time.

A session instance to be used on object **instantiation** can **explicitly** be given as first parameter to the SAGA object instantiation call (`CONSTRUCTOR`).

If the session is omitted as first parameter, a default session is used, with default security context(s) attached. *The default session can be obtained by passing **true** to the session `CONSTRUCTOR`.*

Code Example

```

1      // Example in C++:
2
3      // create a file object in a specific session:
4      saga::file f1 (session, url);
5
6      // create a file object in the default session:
7      saga::file f2 (url);

```

SAGA objects created from *other SAGA objects inherit its* *another SAGA object inherit its* session, such as, for example, `saga::streams` from `saga::stream_server`. Only some objects do not need a session *at* creation time, and can hence be shared between sessions. These include:

```

saga::exception
saga::buffer
saga::iovec
saga::parameter
saga::context
saga::job_description
saga::metric
saga::exception
saga::task
saga::task_container

```

Note that tasks have no explicit session attached. The `saga::object` the task was created from, however, has a `saga::session` attached, *and that session instance is indirectly available, as the application can obtain that object via the `get_object` method call on the respective task instance.*

Multiple sessions can co-exist. *A single session can be shared between threads.*

If a `saga::session` object instance gets destroyed, or goes out of scope, the objects associated with that session survive. The implementation **MUST** ensure that the session is internally kept alive until the last *of that sessions objects* *object of that session* gets destroyed.

If the session object *instance* itself gets destroyed, the resources associated with that session **MUST** be freed immediately as the last object associated with that session gets destroyed. *The lifetime of the default session is, however, only limited by the lifetime of the SAGA application itself (see Notes about life time management in Section 2.5.3).*

Objects associated with different sessions **MUST NOT** influence each other in any way - for all practical purposes, they can be considered to be running in different application instances.

Any SAGA operation CAN throw an `TIncorrectSession` exception if it involves two different session handles.

Instances of the `saga::context` class (which encapsulates security information in SAGA) can be attached to a `saga::session` instance. The context instances are to be used by that session for authentication and authorization to *the* the backends used.

If a `saga::context` gets removed from a session, but that context is already/still used by any object created in that session, the context MAY continue to be used by these objects, and by objects which inherit the session from these objects, but not by any other objects. However, a call to `list_contexts` MUST NOT list the removed context after it *gets got* removed.

For the default `session` instance, of any explicitly attached `saga::context` instances, the list returned by a call to `list_contexts()` MUST include the default `saga::context` instances. These are those contexts that are added to any `saga::session` by default, e.g. because they are picked up by the SAGA implementation from the application's run time environment. An application can, however, subsequently remove default contexts from the default session. A new, non-default session has initially no contexts attached.

A SAGA implementation MUST document *which* default context instances it may create and attach to a `saga::session`. That set MAY change during runtime, but *SHOULD NOT* be changed once a `saga::session` instance was created. *For example*, two `saga::session` instances might have different default `saga::context` instances attached. Both sessions, however, will have these attached for their complete lifetime – *unless they expire or get otherwise invalidated.*

Default `saga::context` instances on a session can be removed from a session, with a call to `remove_context()`. That may result in a session with no contexts attached. *That session is still valid, but likely to fail on most authorization points.*

```

- CONSTRUCTOR
  Purpose:  create the object
!   Format:  CONSTRUCTOR          (in bool    default = true,
                                   out session obj)
+   Inputs:  default:             indicates if the default
+                                   session is returned
+   InOuts:  -
+   Outputs: obj:                 the newly created object
+   PreCond: -
+   PostCond: -
+   Perms:   -

```

```

+   Throws:   NotImplemented
+             NoSuccess
+   Notes:    - the created session has no context
+               instances attached.
+             - if 'default' is specified as 'true', the
+               constructor returns a shallow copy of the
+               default session, with all the default
+               contexts attached. The application can then
+               change the properties of the default session,
+               which is continued to be implicitly used on
+               the creation of all saga objects, unless
+               specified otherwise.

- DESTRUCTOR
  Purpose:   destroy the object
  Format:    DESTRUCTOR          (in session obj)
  Inputs:    obj:                the object to destroy
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: - See notes about lifetime management
+               in Section 2
+   Perms:    -
+   Throws:   -
+   Notes:    -

- add_context
  Purpose:   attach a security context to a session
  Format:    add_context          (in context c);
  Inputs:    c:                  Security context to add
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: - the added context is deep copied, and no
+               state is shared.
+               - any object within that session can use the
+               context, even if it was created before
+               add_context was called.
+   Perms:    -
+   Throws:   NotImplemented
+   Notes:    - if the session already has a context attached
  !           which has exactly the same set of attribute
               values as the parameter context, no action is
               taken.

```

```

- remove_context
  Purpose: detach a security context from a session
!   Format:  remove_context      (in context c);
!   Inputs:  c:                  Security context to remove
+   InOuts:  -
+   Outputs: -
+   Throws:  NotImplemented
              DoesNotExist
+   PreCond: - a context with completely identical attributes
              is available in the session.
+   PostCond: - that context is removed from the session, and
              can from now on not be used by any object in
              that session, even if it was created before
              remove_context was called.
+   Perms:   -
!   Notes:   - this methods removes the context on the
!             session which has exactly the same set of
              parameter values as the parameter context.
              - a 'DoesNotExist' exception is thrown if no
              context exist on the session which has the
              same attributes as the parameter context.

- list_contexts
  Purpose: retrieve all contexts attached to a session
  Format:  list_contexts      (out array<context>
                              contexts);
  Inputs:  -
+  InOuts: -
!  Outputs: contexts:         list of contexts of this
                              session
+  PreCond: -
+  PostCond: -
+  Perms:   -
+  Throws:  NotImplemented
  Notes:   - a empty list is returned if no context is
              attached.
              - contexts may get added to a session by
              default, hence the returned list MAY be
              non-empty even if add_context() was never
              called before.
              - a context might still be in use even if not
              included in the returned list. See notes
              about context life time above.

```

3.5.3 Examples

Code Example

```
1 // c++ example
2 saga::session s;
3 saga::context c (saga::context::X509);
4
5 s.add_context (c);
6
7 saga::directory d (s, "gsiftp://remote.net/tmp/");
8 saga::file f = d.open ("data.txt");
9
10 // file has same session attached as dir,
11 // and can use the same contexts
```

Code Example

```
1 // c++ example
2 saga::task t;
3 saga::session s;
4
5 {
6     saga::context c ("X509");
7
8     s.add_context (c);
9
10    saga::file f (s, url);
11
12    t = f.copy <saga::task::Task> (target);
13
14    s.remove_context (c);
15 }
16
17 // As it leaves the scope, the X509 context gets 'destroyed'.
18 // However, the copy task and the file object MAY continue to
19 // use the context, as its destruction is actually delayed
20 // until the last object using it gets destroyed.
21
22 t.run (); // can still use the context
```

3.6 SAGA Context Management

The `saga::context` class provides the functionality of a security information container. A context is created, and attached to a session handle. As such it is available to all objects instantiated in that session. Multiple contexts can co-exist in one session – it is up to the implementation to choose the correct context for a specific method call. A single `saga::context` instance can be shared between threads and sessions. SAGA objects created from other SAGA objects inherit its session and thus also its context(s). Section 3.5 contains more information about the `saga::session` class, and also about the management and lifetime of `saga::context` instances associated with a SAGA session.

An implementation CAN implement various types of contexts, but MUST implement at least one type. The type of a `saga::context` instance to be created is specified by an enum which is the only argument to the context constructor.

On contexts with type `Unknown`, other methods than `get_type()` should not be called – otherwise an `IncorrectState` exception MUST be thrown.

Every context has a specific set of attributes which can be set/get via the SAGA attributes interface. Exactly what attributes a context offers depends on its type. A context MUST raise an exception if attributes not corresponding to its type are accessed.

The `saga::context` class provides the functionality of a security information container. A context gets created, and attached to a session handle. As such it is available to all objects instantiated in that session. Multiple contexts can co-exist in one session – it is up to the implementation to choose the correct context for a specific method call. Also, a single `saga::context` instance can be shared between threads and multiple sessions. SAGA objects created from other SAGA objects inherit its session and thus also its context(s). Section 3.5 contains more information about the `saga::session` class, and also about the management and lifetime of `saga::context` instances associated with a SAGA session.

A typical usage scenario is:

Code Example

```

1  // context usage scenario in c++
2
3  saga::context c_1, c_2;
4
5  // c_1 will use a globus proxy. Set the type to globus, pick
6  // up the default globus settings, and then identify the proxy
7  // to be used
8  c_1.set_attribute ("Type", "globus");
9  c_1.set_defaults  ();
10 c_1.set_attribute ("UserProxy", "/tmp/special_x509up_u500");
11
12 // c_2 will be used as ssh context, and will just pick up the
13 // public/private key from $HOME/.ssh
14 c_2.set_attribute ("Type", "ssh");
15 c_2.set_defaults  ();
16

```

```
17 // a saga session gets created, and uses both contexts
18 saga::session s;
19 s.add_context (c_1);
20 s.add_context (c_2);
21
22 // a remote file in this session can now be accessed via
23 // gridftp or ssh
24 saga::file f (s, "any://remote.net/tmp/data.txt");
25 f.copy ("data.bak");
```

A context has a set of attributes which can be set/get via the SAGA attributes interface. Exactly which attributes a context actually evaluates, depends upon its type (see documentation to the `set_defaults()` method.

*An implementation CAN implement multiple types of contexts. The implementation MUST document which context types it supports, and which values to the **Type** attribute are used to identify these context types. Also, the implementation MUST document what default values it supports for the various context types, and which attributes need to be or can be set by the application.*

The lifetime of `saga::context` instances **is** defined by the lifetime of those `saga::session` instances **the contexts are** associated with, and of those SAGA objects which have been created in these sessions. For detailed information about lifetime management, see *the introduction* [Section 2.5.3](#), and the description of the SAGA session class in [Section 3.5](#).

For application level *AAA Authorization* (e.g. for streams, monitoring, steering), *read-only* contexts are used to inform the application about the requestor's **identity**. *These contexts represent the security information that has been used to initiate the connection to the SAGA application.* To support that mechanism, a number of specific attributes are available, as specified below. They are named "Remote<attribute>". *An implementation MUST at least set the **Type** attribute for such contexts, and SHOULD provide as many attribute values as possible.*

For example, a SAGA application A creates a `saga::stream_server` instance. A SAGA application B creates a 'globus' type context, and, with a session using that context, creates a `saga::stream` instance connecting to the stream server of A. A should then obtain a context upon connection accept (see [Sections on Monitoring, 3.9](#), and [Streams, 4.5](#), for details). That context should then also have the type 'globus', its 'RemoteID' attribute should contain the distinguished name of the user certificate, and its attributes 'RemoteHost' and 'RemotePort' should have the appropriate values.

*Note that **UserIDs** SHOULD be formatted so that they can be used as user identifiers in the SAGA permission model – see [Section 3.7](#) for details.*

3.6.1 Specification

```
package saga.context
{
-   enum context_type
-   {
-       Unknown          = -1,
-       Globus            = 1, // Globus
-       MyProxy           = 2, // MyProxy
-       SAML              = 3, // SAML
-       Unicore           = 4  // Unicore
-   }
}
```

```

-     SSH                = 5, // SSH
-     Kerberos           = 6, // Kerberos
-     UserPass           = 7 // FTP etc.
- }
-
-     class context : implements saga::object
-                     implements saga::attributes
-                     // from object saga::error_handler
-     {
-     CONSTRUCTOR      (in context_type type,
+     CONSTRUCTOR      (in string         type = "",
+                       out context      obj);
-     DESTRUCTOR       (in context      obj);
-
-     get_ctype        (out context_type type);
+     set_defaults     (void);
-
-     // Attributes:
-     //   name: Type
-     //   desc: type of context
-     //   mode: ReadWrite
-     //   type: String
-     //   value: naming conventions as described above apply
-     //
-     //   name: Server
-     //   desc: server which manages the context
-     //   mode: ReadWrite
-     //   type: String
-     //   value: -
-     //   note: - a typical example would be the contact
-     //           information for a MyProxy server, such as
-     //           'myproxy.remote.net:7512', for a 'myproxy'
-     //           type context.
-     //
-     //   name: CertRepository
-     //   desc: location of certificates and CA signatures
-     //   mode: ReadWrite
-     //   type: String
-     //   value: -
-     //   note: - a typical example for a globus type context
-     //           would be "/etc/grid-security/certificates/".
-     //
-     //   name: UserProxy
-     //   desc: location of an existing certificate proxy to
-     //           be used
-     //   mode: ReadWrite

```

```
! // type: String
! // value: -
! // note: - a typical example for a globus type context
! //           would be "/tmp/x509up_u<uid>".
! //
! // name: UserCert
! // desc: location of a user certificate to use
! // mode: ReadWrite
! // type: String
! // value: -
! // note: - a typical example for a globus type context
! //           would be "$HOME/.globus/usercert.pem".
! //
! // name: UserKey
! // desc: location of a user key to use

!    }
  }
}

```

3.6.2 Specification Details

Class context

*Following attributes **MUST** be supported by the **corresponding** context types, with **examples** for default values given in brackets, where appropriate:*

```
-      Unknown:
-        No attributes supported
-
-      Globus:
-        ReadWrite:
-          UserProxy      (/tmp/x509up_u<uid>)
-          CertLocation   (/etc/grid-security/certificates/)
-          UserCert       ($HOME/.globus/usercert.pem)
-          UserKey        ($HOME/.globus/userkey.pem)
-          UserPass
-        ReadOnly:
-          RemoteID
-          RemoteHost
-          RemotePort
-
-      MyProxy:
-        ReadWrite:
-          Server          (localhost)
-          UserProxy       (/tmp/x509up_u<uid>)
-          UserMyProxy     (/tmp/myproxy-proxy.<uid>.<pid>)
-          CertLocation    (/etc/grid-security/certificates/)
-          UserCert        ($HOME/.globus/usercert.pem)
-          UserKey         ($HOME/.globus/userkey.pem)
-          UserPass
-        ReadOnly:
-          RemoteID
-          RemoteHost
-          RemotePort
-
-      SAML:
-        ReadWrite:
-          UserID
-          UserPass
-        ReadOnly:
-          RemoteID
-          RemoteHost
-          RemotePort
-
-      Unicore:
-        ReadWrite:
-          UserCert        ($HOME/.unicore/keystore)
-          UserPass
-        ReadOnly:
```

```

-         RemoteID
-         RemoteHost
-         RemotePort
-
-
-     SSH:
-         ReadWrite:
-             CertLocation    ($HOME/.ssh/)
-             UserCert        ($HOME/.ssh/id_dsa.pub)
-             UserPass        ($HOME/.ssh/id_dsa)
-         ReadOnly:
-             RemoteID
-             RemoteHost
-             RemotePort
-
-
-     Kerberos:
-         ReadWrite:
-             Server          (localhost)
-             UserID
-             UserPass
-         ReadOnly:
-             RemoteID
-             RemoteHost
-             RemotePort
-
-
-     UserPass:
-         ReadWrite:
-             UserID
-             UserPass
-         ReadOnly:
-             RemoteID
-             RemoteHost
-             RemotePort
-
-     Other context types MAY be specified by a SAGA
-     implementation.
-
-
- - CONSTRUCTOR
-     Purpose:  create a security context
-     Format:   CONSTRUCTOR          (in  context_type type,
-                                     out context      obj);
-     Inputs:  type:                  type of context
-     InOuts:  -

```

```

-   Outputs:  obj:                the newly created object
-   PreCond:  -
-   PostCond: -
-   Perms:    -
-   Throws:   BadParameter
-   Notes:    - BadParameter is thrown if a context type is
-               not supported (NOT NotImplemented).
-
+   - CONSTRUCTOR
+   Purpose:  create a security context
+   Format:   CONSTRUCTOR          (in stringt type = "",
+                                   out context obj);
+   Inputs:   type:                initial type of context
+   InOuts:   -
+   Outputs:  obj:                the newly created object

+  - set_defaults
+    Purpose:  set default values for specified context type
+    Format:    set_defaults          (void);
+    Inputs:    -
+    InOuts:    -
+    Outputs:   -
+    PreCond:   -
+    PostCond:  - the context is valid, and can be used for
+                  authorization.
+    Perms:     -
+    Throws:    NotImplemented
+               IncorrectState
+               Timeout
+               NoSuccess
+    Notes:     - the method avaluates the value of the 'Type'
+                  attribute, and of all other non-empty
+                  attributes, and, based on that information,
+                  tries to set sensible default values for all
+                  previously empty attributes.
+               - if the 'Type' attribute has an empty value, an
+                  'IncorrectState' exception is thrown.
+               - this method can be called more than once on
+                  a context instance.
+               - if the implementation cannot create valid
+                  default values based on the available
+                  information, an 'NoSuccess' exception is
+                  thrown, and a detailed error message is
+                  given, describing why no default values
+                  could be set.
```

3.7 SAGA Permission Model

This whole section has been added to the specification!

A number of SAGA use cases imply the ability of applications to allow or deny specific operations on SAGA objects or grid entities, such as files, streams, or monitorables. This package provides a generic interface to query and set such permissions, for (a) everybody, (b) individual users, and (c) groups of users.

Objects implementing this interface maintain a set of permissions for each object instance, for a set of IDs. These permissions can be queried, and, in many situations, set. The SAGA specification defines which permissions are available on a SAGA object, and which operations are expected to respect these permissions.

A general problem with this approach is that it is difficult to anticipate how users and user groups are identified by various grid middleware systems. In particular, any translation of permissions specified for one grid middleware is likely not completely translatable to permissions for another grid middleware.

For example, assume that a `saga::file` instance gets created via ssh, and permissions are set for the file to be readable and executable by a specific POSIX user group ID. Which implications do these permissions have with respect to operations performed with GridFTP, using a Globus certificate? The used X509 certificates have (a) no notion of groups (groups are implicit due to the mapping of the `grid-mapfile`), and (b) are not mappable to group ids; and (c) GridFTP ignores the executable flag on files.

For this reason, it is anticipated that the permission model described in this section has the following, undesired consequences and limitations:

- Applications using this interface are not expected to be fully portable between different SAGA implementations. (In cases like having two SAGA implementations that use different middleware backends for accessing the same resources.)
- A SAGA implementation MUST document which permission it supports, for which operations.
- A SAGA implementation MUST document if it supports group level permissions.
- A SAGA implementation MUST document how user and group IDs are to be formed.

Note that there are no separate calls to get/set user, group and world permissions: this information must be part of the IDs the methods operate upon. To set/get permissions for 'world' (i.e. anybody), the ID '*' is used.

IDs

SAGA can not, by design, define globally unique identifiers in a portable way. For example, it would be impossible to map, transparently and bi-directionally, a Unix user ID and an associated X509 Distinguished Name on any resource onto the same hypothetical SAGA user ID, at least not without explicit support by the grid middleware (e.g., by having access to the Globus `grid-mapfile`). That support is, however, rarely available.

It is thus required that SAGA implementations **MUST** specify how the user and group IDs are formed that they support. In general, IDs which are valid for the `UserID` attribute of the SAGA context instances **SHOULD** also be valid IDs to be used in the SAGA permission model.

A typical usage scenario is (extended from the context usage scenario):

Code Example

```
1  // context and permission usage scenario in C++
2
3  saga::context c_1 ("globus")
4  saga::context c_2 ("ssh");
5
6  // c_1 is a globus proxy. Identify the proxy to be used,
7  // and pick up the other default globus settings
8  c_1.set_attribute ("UserProxy", "/tmp/special_x509up_u500");
9  c_1.set_defaults ();
10
11 // c_2 is a ssh context, and will just pick up the
12 // public/private key from $HOME/.ssh
13 c_2.set_defaults ();
14
15 // a saga session gets created, and uses both contexts
16 saga::session s;
17 s.add_context (c_1);
18 s.add_context (c_2);
19
20 // a remote file in this session can now be accessed via
21 // gridftp or ssh
22 saga::file f (s, "any://remote.net/tmp/data.txt");
23 f.copy ("data.bak");
24
25 // write permissions can be set for both context IDs
26 f.permission_allow (c_1.get_attribute ("UserID"), Write);
27 f.permission_allow (c_2.get_attribute ("UserID"), Write);
```

For middleware systems where group and user ids can clash, the IDs should be

implemented as `'user-<id>'` and `'group-<id>'`. For example: on Unix, the name `'mail'` can (and often does) refer to a user and a group. In that case, the IDs should be expressed as `'user-mail'` and `'group-mail'`, respectively. The ID `'*'` is always reserved, as described above.

Permissions for a user ID supersede the permissions for a group ID, which supersede the permissions for `'*'` (all). If a user is in multiple groups, and the group's permissions differ, the most permissive permission applies.

3.7.1 Permissions for Multiple Backends

In SAGA, an entity which provides the `permissions` interface always has exactly one owner, for one middleware backend. However, this implies that for SAGA implementations with multiple backend bindings, multiple owner IDs may be valid. For example, `"/O=dutchgrid/O=users/O=vu/OU=cs/CN=Joe Doe"` and `"user-jdoe"` might be equally valid IDs, at the same time, if the implementation supports local Unix access and GridFTP access to a local file. As long as the ID spaces do not conflict, the `permissions` interface obviously allows to set permissions individually for both backends. In case of conflicts, the application would need to create new SAGA objects from sessions that contain only a single context, representing the desired backend's security credentials. As such situations are considered to be very rare exceptions in the known SAGA use cases, we find this limitation acceptable.

Note that, for SAGA implementations supporting multiple middleware backends, the `permissions` interface can operate on permissions for any of these backends, not only for the one that was used by the original creation of the object instance. Such a restriction would basically inhibit implementations with dynamic ("late") binding to backends.

Conflicting Backend Permission Models

Some middleware backends may not support the full range of permissions, e.g., they might not distinguish between `Query` and `Read` permissions. A SAGA implementation **MUST** document which permissions are supported. Trying to set an unsupported permission results in a `BadParameter` exception, and **NOT** in a `NotImplemented` exception – that would indicate that the method is not available at all, i.e. that no permission model at all is available for this particular implementation.

An implementation **MUST NOT** silently merge permissions, according to its own model – that would break for example the following code:

```
file.permissions_allow ("user-jdoe", Query);
file.permissions_deny  ("user-jdoe", Read );
off_t file_size = file.get_size ();
```

If an implementation binds to a system with standard Unix permissions and does not throw a **BadParameter** exception on the first call, but silently sets **Read** permissions instead, because that does also allow query style operations on Unix, then the code in line three would fail for no obvious reason, because the second line would revoke the permissions from line one.

Initial Permission Settings

If new grid entities get created via the SAGA API, the owner of the object is set to the value of the '**UserID**' attribute of the context used during the creation. Note that for SAGA implementations with support for multiple middleware backends, and support for late binding, this may imply that the owner is set individually for one, some or all of the supported backends.

Creating grid entities may require specific permissions on other entities. For example:

- file creation requires **Write** permissions on the parent directory.
- executing a file requires **Read** permissions on the parent directory.

An implementation **CAN** set initial permissions other than **Owner**. An implementation **SHOULD** document which initial permission settings an application can expect.

The specification of the **ReadOnly** flag on the creation or opening of SAGA object instances, such as **saga::file** instances, causes the implementation to behave as if the **Write** permission on the entity on that instance is not available, even if it is, in reality, available. The same holds for the **WriteOnly** flag and the availability of the **Read** permission on that entity.

Permission Definitions in the SAGA specification

The SAGA specification normatively defines for each operation, which permissions are required for that operation. If a permission is supported, but not set, the method invocation **MUST** cause a **PermissionDenied** exception. An implementation **MUST** document any deviation from this scheme, e.g., if a specified

permission is not supported at all, or cannot be tested for a particular method. An example of such a definition is (from the `monitorable` interface):

```

- list_metrics
  Purpose: list all metrics associated with the object
  Format:  list_metrics      (out array<string>  names);
  Inputs:  -
  InOuts:  -
  Outputs: names:            array of names identifying
                               the metrics associated with
                               the object instance

  PreCond: -
  PostCond: -
  Perms:   Query
  Throws:  NotImplemented
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:   - [...]

```

This example implies that for the session in which the `list_metrics()` operation gets performed, there must be at least one context for which's attribute 'UserID' the `Query` permission is both supported and available; otherwise, the method **MUST** throw a `PermissionDenied` exception. If `Query` is not supported by any of the backends for which a context exists, the implementation **MAY** try the backends to perform the operation anyway.

For some parts of the specification, namely for attributes and metrics, the `mode` specification is normative for the respective, required permission. For example, the mode attribute `ReadOnly` implies that a `Write` permission, required to change the attribute, is never available.

The `PermissionDenied` exception in SAGA

SAGA supports a `PermissionDenied` exception, as documented in Section 3.1. This exception can originate from various circumstances, that are not necessarily related to the SAGA permission model as described here. However, if the reason why that exception is raised maps onto the SAGA permission model, the exception's error message **MUST** have the following format (line breaks added for readability):

```
PermissionDenied: no <PERM> permission
                  on <ENTITY> <NAME>
                  for <ID>
```

Here, <PERM> denotes which permission is missing, <ENTITY> denotes on what kind of entity this permission is missing. <NAME> denotes which entity misses that permission, and <ID> denotes which user is missing that permission.

<PERM> is the literal string of the `permission` enum defined in this section. <ENTITY> is the type of backend entity which is missing the permission, e.g. `file`, `directory`, `job_service` etc. Whenever possible, the literal class name of the respective SAGA class name SHOULD be used. <NAME> SHOULD be a URL or literal name which allows the end user to uniquely identify the entity in question. <ID> is the value of the `UserID` attribute of the context used for the operation (the notes about user IDs earlier in this section apply).

Some examples for complete error messages are:

```
PermissionDenied: no Read permission
                  on file http:///tmp/test.dat
                  for user-jdoe

PermissionDenied: no Write permission
                  on directory http:///tmp/
                  for user-jdoe

PermissionDenied: no Query permission
                  on logical_file rls:///tmp/test
                  for /O=ca/O=users/O=org/CN=Joe Doe

PermissionDenied: no Query permission
                  on job [fork://localhost]-[1234]
                  for user-jdoe

PermissionDenied: no Exec permission
                  on RPC [rpc://host/matmult] for
                  for /O=ca/O=users/O=org/CN=Joe Doe
```

Note to users

The description of the SAGA permission model above should have made clear that, in particular, the support for multiple backends makes it difficult to strictly enforce the permissions specified on application level. Until a standard for permission management for Grid application emerges, this situation is unlikely to change. Applications should thus be careful to trust permissions specified in SAGA, and should ensure to use an implementation which fully supports

and enforces the permission model, e.g., they should choose an implementation which binds to a single backend.

3.7.2 Specification

```
package saga.permissions
{
  enum permission
  {
    None      = 0,
    Query     = 1,
    Read      = 2,
    Write     = 4,
    Exec      = 8,
    Owner     = 16,
    All       = 31
  }

  interface permissions : implements saga::async
  {
    // setter / getters
    permissions_allow      (in string      id,
                           in int         perm);
    permissions_deny       (in string      id,
                           in int         perm);
    permissions_check      (in string      id,
                           in int         perm,
                           out bool       value);
    get_owner              (out string     owner);
    get_group              (out string     group);
  }
}
```

3.7.3 Specification Details

Enum permission

This enum specifies the available permissions in SAGA. The following examples demonstrate which type of operations are allowed for certain permissions, and which aren't. To keep these examples concise, they are chosen from the following

list, with the convention that those operations in this list, which are not listed in the respective example section, are *not* allowed for that permission. In general, the availability of one permission does not imply the availability of any other permission (with the exception of **Owner**, as described below).

- provide information about a metric, and its properties
- provide information about file size, access time and ownership
- provide information about job description, ownership, and runtime
- provide information about logical file access time and ownership
- provide access to a job's I/O streams
- provide access to the list of replicas of a logical file
- provide access to the contents of a file
- provide access to the value of a metric
- provide means to change the ownership of a file or job
- provide means to change the permissions of a file or job
- provide means to fire a metric
- provide means to connect to a stream server
- provide means to manage the entries in a directory
- provide means to manipulate a file or its meta data
- provide means to manipulate a job's execution or meta data
- provide means to manipulate the list of replicas of a logical file
- provide means to run an executable

The following permissions are available in SAGA:

Query

This permission identifies the ability to *access all meta data of an entity*, and thus to obtain any information about an entity. If that permission is not available for an actor, that actor **MUST NOT** be able to obtain any information about the queried entity, if possible not even about its existence. If that permission is available for an actor, the actor **MUST** be able to query for any meta data on the object which (a) do imply changes on the entities state, and (b) are part of the *content* of the entity (i.e., do not comprise its data).

Note that for logical files, attributes are part of the data of the entities (i.e., the meta data belong to the logical file's data).

An authorized **Query** operation can:

- provide information about a metric, and its properties
- provide information about file size, access time and ownership

- provide information about job description, ownership, and runtime
- provide information about logical file access time and ownership

Read

This permission identifies the ability to *access the contents and the output of an entity*. If that permission is not available for an actor, that actor **MUST NOT** be able to access the data of the entity. That permission does not imply the authorization to change these data, or to manipulate the entity. That permission does also not imply **Query** permissions, i.e. the permission to access the entity's meta data.

An authorized **READ** operation can:

- provide access to a job's I/O streams
- provide access to the list of replicas of a logical file
- provide access to the contents of a file
- provide access to the value of a metric

Write

This permission identifies the ability to *manipulate the contents of an entity*. If that permission is not available for an actor, that actor **MUST NOT** be able to change neither data nor meta data of the entity. That permission does not imply the authorization to read these data of the entity, nor to manipulate the entity. That permission does also not imply **Query** permissions, i.e., the permission to access the entity's meta data.

Note that, for a directory, its entries comprise its data. Thus, **Write** permissions on a directory allow to manipulate all entries in that directory – but do not imply the ability to change the data of these entries. For example, **Write** permissions on the directory `'/tmp'` allows to move `'/tmp/a'` to `'/tmp/b'`, or to remove these entries, but does not imply the ability to perform a `read()` operation on `'/tmp/a'`.

An authorized **Write** operation can:

- provide means to manage the entries in a directory
- provide means to manipulate a file or its meta data
- provide means to manipulate a job's execution or meta data
- provide means to manipulate the list of replicas of a logical file

Exec

This permission identifies the ability to *perform an action on an entity*. If that permission is not available for an actor, that actor **MUST NOT** be able to perform that action. The actions covered by that permission are usually those which affect the state of the entity, or which create a new entity.

An authorized **Exec** operation can:

- provide means to fire a metric

- provide means to connect to a stream server
- provide means to run an executable

Owner

This permission identifies the ability to *change permissions and ownership of an entity*. If that permission is not available for an actor, that actor **MUST NOT** be able to change any permissions or the ownership of an entity. As this permission indirectly implies full control over all other permissions, it does also imply that an actor with that permission can perform *any* operation on the entity. **Owner** is not listed as additional required permission in the specification details for the individual methods, but only listed for those methods, where **Owner** is an explicit permission requirement which cannot be replaced by any other permission.

An authorized **Owner** operation can:

- provide means to change the ownership of a file or job
- provide means to change the permissions of a file or job
- perform *any* other operation, including all operations from the original list of examples above

Note that only one user can own an entity. For example, the following sequence:

```
file.permissions_allow ("Tarzan", saga::permission::Owner);
file.permissions_allow ("Jane",    saga::permission::Owner);
```

would result in a file ownership by 'Jane'.

Also note that

```
file.permissions_allow ("*", saga::permission::Owner);
```

or

```
file.permissions_deny (id, saga::permission::Owner);
```

will never be possible, and will throw a `BadParameter` exception.

Interface permissions

```
- permissions_allow
Purpose:  enable permission flags
Format:   permissions_allow    (in  string    id,
                                in  int       perm);
Inputs:   id:                  id to set permission for
          perm:                 permissions to enable
InOutputs: -
Outputs:  -
```

```
PreCond: -
PostCond: - the permissions are enabled.
Perms:    Owner
Throws:   NotImplemented
          BadParameter
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes:    - an id '*' sets the permissions for all (world)
          - whether an id is interpreted as a group id is up to
            the implementation. An implementation MUST
            specify how user and group id's are formed.
          - the 'Owner' permission can not be set to the
            id '*' (all).
          - if the given id is unknown or not supported, a
            'BadParameter' exception is thrown.
```

```
- permissions_deny
Purpose:  disable permission flags
Format:   permissions_deny      (in string      id,
                                in int          perm);

Inputs:   id:                   id to set permissions for
          perm:                  permissions to disable

InOuts:   -
Outputs:   -
PreCond:   -
PostCond:  - the permissions are disabled.
Perms:     Owner
Throws:    NotImplemented
          BadParameter
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes:    - an id '*' sets the permissions for all (world)
          - whether an id is interpreted as a group id is up to
            the implementation. An implementation MUST
            specify how user and group id's are formed.
          - the 'Owner' permission can not be set to the
            id '*' (all).
          - if the given id is unknown or not supported, a
            'BadParameter' exception is thrown.
```

```
- permissions_check
Purpose:  check permission flags
Format:  permissions_check  (in string    id,
                             in int       perm,
                             out bool     allow);

Inputs:   id:                id to check permissions for
          perm:              permissions to check
InOuts:   -
Outputs:  allow:            indicates if, for that id,
                             the permissions are granted
                             (true) or not.

PreCond:  -
PostCond: -
Perms:    Query
Throws:   NotImplemented
          BadParameter
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes:    - an id '*' gets the permissions for all (world)
          - 'true' is only returned when all permissions
            specified in 'perm' are set for the given id.
          - if the given id is unknown or not supported, a
            'BadParameter' exception is thrown.

- get_owner
Purpose:  get the owner of the entity
Format:  get_owner          (out string    owner);
Inputs:   -
InOuts:   -
Outputs:  owner:            id of the owner
PreCond:  -
PostCond: -
Perms:    Query
Throws:   NotImplemented
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes:    - returns the id of the owner of the entity
```

- an entity, on which the permission interface is available, always has exactly one owner: this method MUST NOT return an empty string, and MUST NOT return '*' (all), and MUST NOT return a group id.
- get_group
 - Purpose: get the group owning the entity
 - Format: get_group (out string group);
 - Inputs: -
 - InOuts: -
 - Outputs: group: id of the group
 - PreCond: -
 - PostCond: -
 - Perms: Query
 - Throws: NotImplemented
 - PermissionDenied
 - AuthorizationFailed
 - AuthenticationFailed
 - Timeout
 - NoSuccess
 - Notes:
 - returns the id of the group owning the entity
 - this method MUST NOT return '*' (all), and MUST NOT return a user id.
 - if the implementation does not support groups, the method returns an empty string.

3.7.4 Examples

Code Example

```

1 // c++ example
2 {
3     // create a file in the default session
4     saga::file f (url, saga::file::Create
5                   | saga::file::Exclusive);
6
7
8     // get all contexts of the default session, and for each...
9     std::list <saga::context> ctxs = theSession.list_contexts ();
10
11     for ( int i = 0; i < ctxs.size (); i++ )
12     {
13         saga::context ctx = ctxs[i];

```

```
14
15      // set the file to be executable
16      f.permission_allow (ctx.get_attribute ("UserID"),
17                          saga::permission::Exec);
18  }
19
20  // the file should now be usable for job submission for all
21  // contexts in the default session. Often, however, only
22  // one context will succeed in setting the permission: the
23  // one which was used for creation in the first place. In
24  // that case, job submission is most likely to succeed with
25  // that context, too.
26  }
```

3.8 SAGA Attribute Model

There are various places in the SAGA API where attributes need to be associated with objects, for instance for job descriptions and metrics. The **attributes** interface provides a common interface for storing and retrieving attributes.

Objects implementing this interface maintain a set of attributes. These attributes can be considered as a set of key-value pairs attached to the object. The key-value pairs are string based for now, but might cover other value types in later versions of the SAGA API specification.

The interface **name attributes** is somewhat misleading: it seems to imply that an object implementing this interface **IS** a set of attributes. What we actually mean is that an object implementing this interface **HAS** attributes. *For want* *In the absence* of a better name, we left it **attributes**, but **implementors** and users should be aware of the actual meaning (**the** proper interface **name** would be 'attributable', which sounds awkward).

The SAGA *specification* defines attributes which **MUST** be supported by the various SAGA objects, and *also defines* their default values, and *also defines* those which **CAN** be supported. An implementation **MUST** motivate and document if a specified attribute is not supported.

3.8.1 Specification

```

package saga.attributes
{
    interface attributes
    {
        // setter / getters
        set_attribute      (in  string      key,
                           in  string      value);

        get_attribute      (in  string      key,
                           out string      value);

        set_vector_attribute (in  string      key,
                              in  array<string> values);

        get_vector_attribute (in  string      key,
                              out array<string> values);

        remove_attribute    (in  string      key);

        // inspection methods
        list_attributes      (out array<string> keys);
!    find_attributes        (in  array<string> pattern,

```

```

-           in string      val_pattern,
            out array<string> keys);
    attribute_exists      (in string      key,
                          out bool      test);
    attribute_is_readonly (in string      key,
                          out bool      test);
    attribute_is_writable  (in string      key,
                          out bool      test);
    attribute_is_removable (in string      key,
                          out bool      test);
    attribute_is_vector   (in string      key,
                          out bool      test);
-   attribute_equals      (in string      key,
-                           in string      value,
-                           out bool      test);
    }
}

```

3.8.2 Specification Details

The `attributes` interface in SAGA provides a uniform paradigm to set and query parameters and properties of SAGA objects. Although the `attributes` interface is generic by design (i.e. it allows arbitrary keys and values to be used), its use in SAGA is mostly limited to a finite and well defined set of keys.

In several languages, attributes can much more elegantly *be* expressed by native means - e.g. by using hash tables in Perl. Bindings for such languages MAY allow to use a native interface *additionally* to the one described here.

Several SAGA objects have very frequently used attributes. To simplify usage of these objects, setter and getter methods MAY be defined by the various language bindings, again *additionally* to the interface described below. For attributes of native non-string types, these setter/getters MAY be typed.

For example, additionally to:

```
stream.set_attribute ("BufferSize", "1024");
```

a language binding might allow:

```
stream.set_buffer_size (1024); // int type
```

Further, in order to limit semantic and syntactic ambiguities (e.g., due to spelling deviations), language bindings MUST define known attribute keys as constants, such as (in C):

```
#define SAGA_BUFFERSIZE "BufferSize"
...
stream.set_attribute (SAGA_BUFFERSIZE, "1024");
```

The distinction between scalar and vector attributes is *somewhat artificial, and is* supposed to help those languages where *that nature* *this aspect* of attributes cannot be handled transparently, e.g. by overloading. Bindings for languages such as Python, Perl and C++ CAN hide *this* distinction as long as both access types are supported.

To simplify handling of scalar/vector attributes, vector attributes can be specified as comma delimited strings (leading space after comma is ignored, unless escaped):

```
val 1: "home, sweet home"
val 2: "Open GF"
val 3: " SAGA"
string: "home sweet home, Open GF, SAGA"
```

That format is returned if scalar getters are used for vector attributes, and can be used for scalar setters for vector attributes. Vector setters/getters handle scalar attributes as vectors of length one.

The order of the elements of vector attributes is well defined, and *Elements of vector attributes are ordered.* *This order* MUST be preserved by the SAGA implementation. *Comparison* also relies on ordering (i.e. 'one two' does not equal 'two one'). For example, *this* order is significant for the `saga::job_description` attribute 'Arguments', which represents command line arguments for a job.

Attributes are expressed as string values. They have, *however*, a type, which defines the formatting of that string. The allowed types are `String`, `Int`, `Enum`, `Float`, `Bool`, and `Time` (the same as metric value types). Additionally, *attributes* are qualified as either `Scalar` or `Vector`. The default is `Scalar`.

Values of `String` type attributes are expressed as-is. *however, comma, backslashes and leading spaces need to be escaped by a backslash, as described above.*

Values of `Int` (i.e. Integer) type attributes are expressed as they would in result of a printf of the format `'%ld'`, as defined by POSIX.

Values of `Enum` type attributes are expressed as strings, and have the literal value of the respective enums as defined in this document. For example, the initial task states would have the values 'New', 'Running' and 'Done'.

Values of `Float` (*i.e. floating* point) type attributes are expressed as they would in result of a printf of the format `'%Lf'`, as defined by POSIX.

Values of `Bool` type attributes MUST be expressed as 'True' or 'False'.

Values of **Time** type attributes MUST be expressed as they would in result of a call to `ctime()`, as defined by POSIX. Applications can also specify these attribute values as seconds since epoch (this **formats** the string as **an Int** type), but all time attributes set by the implementation MUST be in `ctime()` format. Applications should be aware of the `strptime()` and `strftime()` methods defined in POSIX, which assist time conversions.

3.8.3 Attribute Definitions in the SAGA specification

The SAGA specification defines a number of attributes which MUST or CAN be supported, for various SAGA objects. An example *of* such a definition is (from the Metric object):

```
class metric ...
{
    ...

    // Attributes:
    //   name:   Name
    //   desc:   name of metric
    //   mode:   ReadOnly
    //   type:   String
    //   value:  -
    //   notes:  naming conventions as described below apply
    //
    //   ...
}
```

These specifications are **NORMATIVE**, even if described as comments in the SIDL specification! The specified attributes MUST be supported by an implementation, unless noted otherwise, as:

```
// mode:  ReadOnly, optional
// mode:  ReadWrite, optional
```

If an attribute MUST be supported, but the SAGA implementation cannot support that attribute, any set/get on that attribute MUST throw a `NotImplemented` exception, and the error message MUST state "**Attribute <name> not available in this implementation**".

If the default value is *denoted as '-'*, then the attribute *is, by default, not set at all*. *Non-optional attributes MUST have a default value (which can be an empty string).*

Attribute support can 'appear' and 'go away' during the lifetime of an object (e.g., as late binding implementations switch the backend). Any set on **an** attribute which got removed ('dead attribute') MUST throw a **DoesNotExist** exception. However, dead attributes MUST stay available for read access. The SAGA implementation MUST NOT change *that such an* attribute's value, as long as it is not available. Allowed values for mode are **ReadOnly** and **ReadWrite**.

It is not allowed to add attributes other **than** those specified in this document, unless **explicitly** allowed, as:

```
// Attributes (extensible):
```

The `find_attributes()` method accepts *a list* of patterns, and returns a list of keys for those attributes which **match** any one of the specified patterns (OR **semantics**). The *allowed* patterns *describe both attribute keys and values*, and are *formatted as*:

```
<key-pattern>=<value-pattern>
```

*Both the **key-pattern** and the **value-pattern** can contain wildcards as defined in the description of the SAGA namespace package e. If a **key-pattern** contains an '=' character, that character must be escaped by a backslash, as must any backslash character itself. The **value-pattern** can be empty, and the method will then return all attribute keys which match the **key-pattern**. The equal sign '=' can then be omitted from the pattern.*

Interface attributes

```
- set_attribute
  Purpose:  set an attribute to a value
  Format:   set_attribute      (in string key,
                               in string value);
  Inputs:   key:              attribute key
            value:            value to set the
                               attribute to
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: -
+   Perms:   Write
+   Throws:  NotImplemented
            BadParameter
            DoesNotExist
-           ReadOnly
```

```

+      IncorrectState
+      PermissionDenied
+      AuthorizationFailed
+      AuthenticationFailed
+      Timeout
+      NoSuccess
!      Notes:
-      an empty string means to set an empty value
        (the attribute is not removed).
-      the attribute is created, if it does not exist
-      a 'PermissionDenied' exception is thrown if the
        attribute to be changed is ReadOnly.
-      only some SAGA objects allow to create new
        attributes - others allow only access to
        predefined attributes. If a non-existing
        attribute is queried on such objects, a
        'DoesNotExist' exception is raised
-      changes of attributes may reflect changes of
        endpoint entity properties. As such,
!      authorization and/or authentication may fail
!      for settings such attributes, for some
!      backends. In that case, the respective
        'AuthenticationFailed', 'AuthorizationFailed',
        and 'PermissionDenied' exceptions are thrown.
!      For example, an implementation may forbid to
        change the saga::stream 'Bufsize' attribute.
-      if an attribute is not well formatted, or
        outside of some allowed range, a 'BadParameter'
        exception with a descriptive error message is
        thrown.
+      - if the operation is attempted on a vector
+      attribute, an 'IncorrectState' exception is
+      thrown.
-      setting of attributes may time out, or may fail
        for other reasons - which causes a 'Timeout' or
        'NoSuccess' exception, respectively.

- get_attribute
! Purpose: get an attribute value
Format: get_attribute      (in string key,
                           out string value);
Inputs: key:               attribute key
+ InOuts: -
Outputs: value:            value of the attribute
+ PreCond: -
+ PostCond: -

```

```

+   Perms:    Query
+   Throws:   NotImplemented
+             DoesNotExist
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
!   Notes:   - queries of attributes may imply queries of
!             endpoint entity properties. As such,
!             authorization and/or authentication may fail
!             for querying such attributes, for some
!             backends. In that case, the respective
!             'AuthenticationFailed', 'AuthorizationFailed',
!             and 'PermissionDenied' exceptions are thrown.
!             For example, an implementation may forbid to
!             read the saga::stream 'Bufsize' attribute.
+             - reading an attribute value for an attribute
+               which is not in the current set of attributes
+               causes a 'DoesNotExist' exception.
+             - if the operation is attempted on a vector
+               attribute, an 'IncorrectState' exception is
+               thrown.
+             - getting attribute values may time out, or may
+               fail for other reasons - which causes a
+               'Timeout' or 'NoSuccess' exception,
+               respectively.

- set_vector_attribute
  Purpose:  set an attribute to an array of values.
  Format:   set_vector_attribute (in string      key,
                                in array<string> values);
  Inputs:   key:      attribute key
            values:    array of attribute values
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: -
+   Perms:   Write
+   Throws:  NotImplemented
+           BadParameter
+           DoesNotExist
-           ReadOnly
+           IncorrectState

```

```

        PermissionDenied
        AuthorizationFailed
        AuthenticationFailed
        Timeout
        NoSuccess
    Notes:  - the notes to the set_attribute() method apply.
+         - if the operation is attempted on a scalar
+           attribute, an 'IncorrectState' exception is
+           thrown.

- get_vector_attribute
  Purpose: get the array of values associated with an
           attribute
  Format:  get_vector_attribute (in string      key,
                                out array<string> values);
  Inputs:  key:                  attribute key
+  InOuts: -
  Outputs: values:              array of values of the
                                attribute.

+  PreCond: -
+  PostCond: -
+  Perms:   Query
+  Throws:  NotImplemented
           DoesNotExist
+           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:   - the notes to the get_attribute() method apply.
+         - if the operation is attempted on a scalar
+           attribute, an 'IncorrectState' exception is
+           thrown.

- remove_attribute
  Purpose: removes an attribute.
  Format:  remove_attribute      (in string key);
  Inputs:  key:                  attribute to be removed
+  InOuts: -
  Outputs: -
+  PreCond: -
+  PostCond: - the attribute is not available anymore.
+  Perms:   Write

```

```

+   Throws:   NotImplemented
              DoesNotExist
-   ReadOnly
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
      Notes:   - a vector attribute can also be removed with
                  this method
                  - only some SAGA objects allow to remove
                    attributes.
                  - a ReadOnly attribute cannot be removed - any
!   attempt to do so throws a 'PermissionDenied'
                    exception.
                  - if a non-existing attribute is removed, a
                    'DoesNotExist' exception is raised.
                  - exceptions have the same semantics as defined
                    for the set_attribute() method description.

- list_attributes
  Purpose:    Get the list of attribute keys.
  Format:     list_attributes      (out array<string>   keys);
  Inputs:     -
+   InOuts:   -
  Outputs:    keys:                existing attribute keys
+   PreCond:   -
+   PostCond:  -
+   Perms:     Query
+   Throws:    NotImplemented
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
      Notes:   - exceptions have the same semantics as defined
                  for the get_attribute() method description.
                  - if no attributes are defined for the object,
                    an empty list is returned.

- find_attributes
  Purpose:    find matching attributes.
!   Format:    find_attributes      (in  array<string>  pattern,
-                                     in  array<string>  val_pattern,

```

```

!      Inputs:  pattern:          out array<string>  keys);
-      val_pattern:          search patterns
+      InOuts:  -              value search pattern
+      Outputs: keys:          matching attribute keys
+      PreCond: -
+      PostCond: -
+      Perms:   Query
+      Throws:  NotImplemented
                BadParameter
                PermissionDenied
                AuthorizationFailed
                AuthenticationFailed
                Timeout
                NoSuccess
      Notes:   - the pattern must be formatted as described
                earlier, otherwise a 'BadParameter' exception
                is thrown.
                - exceptions have the same semantics as defined
                  for the get_attribute() method description.

+  - attribute_exists
+  Purpose:  check the attribute's existence.
+  Format:   attribute_exists    (in string key,
+                                out bool  test);
+  Inputs:   key:                attribute key
+  InOuts:   -
+  Outputs:  test:                bool indicating success
+  PreCond:  -
+  PostCond: -
+  Perms:    Query
+  Throws:    NotImplemented
                PermissionDenied
                AuthorizationFailed
                AuthenticationFailed
                Timeout
                NoSuccess
+  Notes:    - This method returns TRUE if the attribute
+              identified by the key exists.
+              - exceptions have the same semantics as defined
+                for the get_attribute() method description,
+                apart from the fact that a DoesNotExist
+                exception is never thrown.
+
+

```

```
- attribute_is_readonly
! Purpose: check the attribute mode.
Format: attribute_is_readonly(in string key,
                              out bool test);

Inputs: key: attribute key
+ InOuts: -
! Outputs: test: bool indicating success
+ PreCond: -
+ PostCond: -
+ Perms: Query
+ Throws: NotImplemented
          DoesNotExist
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes: - This method returns TRUE if the attribute
        identified by the key exists, and can be read
        by get_attribute() or get_vector attribute(),
        but cannot be changed by set_attribute() and
        set_vector_attribute().
        - exceptions have the same semantics as defined
        for the get_attribute() method description.

- attribute_is_writable
! Purpose: check the attribute mode.
Format: attribute_is_writable(in string key,
                              out bool test);

Inputs: key: attribute key
+ InOuts: -
! Outputs: test: bool indicating success
+ PreCond: -
+ PostCond: -
+ Perms: Query
+ Throws: NotImplemented
          DoesNotExist
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess

Notes: - This method returns TRUE if the attribute
        identified by the key exists, and can be
!        changed by set_attribute() or
```

```

        set_vector_attribute().
    - exceptions have the same semantics as defined
      for the get_attribute() method description.

- attribute_is_removable
!   Purpose:  check the attribute mode.
      Format:  attribute_is_removable (in  string key,
                                     out bool  test);
      Inputs:  key:                    attribute key
+   InOuts:   -
!   Outputs:  test:                    bool indicating success
+   PreCond:  -
+   PostCond: -
+   Perms:    Query
+   Throws:   NotImplemented
              DoesNotExist
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
      Notes:  - This method returns TRUE if the attribute
                identified by the key exists, and can be
                removed by remove_attribute().
              - exceptions have the same semantics as defined
                for the get_attribute() method description.

- attribute_is_vector
      Purpose:  check the
      Format:  attribute_is_vector (in  string key,
                                   out bool  test);
      Inputs:  key:                    attribute key
+   InOuts:   -
      Outputs: test                    bool indicating if
                                   attribute is scalar
                                   (false) or vector (true)

-    Throws:   DoesNotExist
-              PermissionDenied
-              AuthorizationFailed
-              AuthenticationFailed
-              Timeout
-              NoSuccess
-
-    Notes:   - This method returns TRUE if the attribute
-              identified by key has the value identified
-              by value
-              - exceptions have the same semantics as defined
-              for the get_attribute() method description.
-

```

3.8.4 Examples

Code Example

```

1  // c++ example:
2  saga::job::description jd;
3
4  std::list<std::string> hosts;
5  hosts.push_back ("host_1");
6  hosts.push_back ("host_2");
7

```

```
8  // vector attributes
9  jd.set_attribute ("ExecutionHosts", hosts);
10
11 // scalar attribute
12 jd.set_attribute ("MemoryUsage", "1024");
13
14 ...
```

3.9 SAGA Monitoring Model

The ability to query **grid** entities about state is requested in several SAGA use cases. Also, the SAGA task model introduces numerous new use cases for state monitoring.

This package definition approaches the problem space of monitoring to unify the various usage patterns (see details and examples), and to transparently incorporate SAGA task monitoring. The paradigm is realised by introducing monitorable SAGA objects, which expose *metrics* to the application, **representing** values to be monitored. *Metrics thus represent monitorable entities.*

A closely related topic is Computational Steering, which is (for our purposes) not seen independently from Monitoring: in the SAGA approach, the steering mechanisms extend the monitoring mechanisms **with** the ability to push values back to the monitored entity, i.e. to introduce writable metrics (see `fire()`). *Thus, metrics can also represent steerable entities.*

3.9.1 Specification

```
! package saga.monitoring
{
!   // callbacks are used for asynchronous notification of
   // metric changes (events)
   interface callback
   {
       cb          (in monitorable    mt,
                   in metric         metric,
                   in context        ctx,
                   out bool          keep);
   }

   // a metric represents an entity / value to be monitored.
   class metric : implements saga::object
       implements saga::attributes
       // from object saga::error_handler
   {
       CONSTRUCTOR      (in string      name,
                       in string      desc,
                       in string      mode,
                       in string      unit,
                       in string      type,
```

```

                                in  string      value,
!                                out metric      obj);
!    DESTRUCTOR                (in  metric      obj);

    // callback handling
    add_callback                (in  callback    cb,
                                out int         cookie);
    remove_callback             (in  int         cookie);

    // actively signal an event
    fire                        (void);

    // Attributes:
    //   name:  Name
!   //   desc: name of the metric
    //   mode: ReadOnly
    //   type: String
    //   value: -
    //   notes: naming conventions as described below apply
    //
    //   name:  Description
!   //   desc: description of the metric
    //   mode: ReadOnly
    //   type: String
    //
    //   name:  Mode
!   //   desc: access mode of the metric
    //   mode: ReadOnly

    //   type: String
    //
    //   name:  Type
!   //   desc: value type of the metric
    //   mode: ReadOnly
    //   type: String
    //   value: 'String', 'Int', 'Enum', 'Float', 'Bool',
    //           'Time' or 'Trigger'
    //
    //   name:  Value
!   //   desc: value of the metric

```

```

    // mode: depending on the mode attribute above
    // type: String
    // value: -
    // notes: see description of value formating below
}

// SAGA objects which provide metrics and can thus be
// monitored implement the monitorable interface
interface monitorable
{
    // introspection
    list_metrics      (out array<string>  names);
    get_metric        (in  string          name,
                      out metric          metric);

    // callback handling
    add_callback      (in  string          name,
                      in  callback        cb,
                      out int             cookie);
    remove_callback   (in  int            cookie);
}

// SAGA objects which can be steered by changing their
// metrics implement the steerable interface
interface steerable : implements monitorable
{
    // metric handling
    add_metric        (in  metric          metric,
                      out bool            success);
    remove_metric     (in  string          name);
    fire_metric        (in  string          name);
}
}

```

3.9.2 Specification Details

Interface callback

The callback interface is supposed to be implemented by custom, application level classes. Instances of these classes can then **be** passed to monitorable SAGA objects, in order to have their `cb` method invoked on changes of metrics **upon** these monitorables.

The callback classes can maintain state between initialization and successive **invocations**. The implementation **MUST** ensure that a callback is only called once at a time, so that no locking is necessary for the end user.

If an invoked callback returns true, it stays registered and can be invoked again on the next metric change. If it returns false, it is not invoked again.

A callback can throw **an AuthorizationFailed** exception if the passed context (i.e. the remote party) is not deemed trustworthy. In this case, the callback is not removed. *The implementation MUST catch this exception, and interpret it as a decline of the operation which caused the callback.*

For example, if a `saga::stream_server` instance invokes a callback on a Client-Connect metric, and the `cb` method raises **an AuthorizationFailed** exception, the created client stream must be closed.

As another example, if a job instance invokes a callback on a MemoryUsage metric, and the `cb` method raises **an AuthorizationFailed** exception, the previous value of the memory usage metric **MUST** be restored, and the declined value **MUST NOT** influence the memory high water mark. **Essentially**, the exception indicates that the new metric value was not trustworthy.

Callbacks are passed (e.g. added to a metric) by reference. If a callback instance is used *multiple times with multiple metrics*, the application must use appropriate locking mechanisms.

```

- cb
!   Purpose: asynchronous handler for metric changes
      Format:  cb                      (in monitorable mt,
                                      in metric      metric,
                                      in context    ctx,
                                      out bool      keep);
      Inputs:  mt:                      the saga monitorable object
!                                     which causes the callback
                                      invocation
                                      metric:      the metric causing the
                                      callback invocation
                                      ctx:          the context associated with
                                      the callback causing entity
+   InOuts:   -
      Outputs: keep:                    indicates if callback stays
                                      registered
+   PreCond:  - the passed context is authenticated.
+   PostCond: - if 'keep' is returned as true, the callback
!               stays registered, and will be invoked again on

```

```
!           the next metric update.
!           - if 'keep' is returned as false, the callback
!             gets unregistered, and will not be invoked
!             again on metric updates, unless it gets
!             re-added by the user.
+   Perms:   -
+   Throws:  NotImplemented
            AuthorizationFailed
   Notes:    - 'metric' is the metric the callback is
              invoked on - that means that this metric
              recently changed. Note that this change is
              semantically defined by the metric, e.g. the
              string of the 'value' attribute of the metric
              might have the same value in two subsequent
              invocations of the callback.
              - 'mt' is the monitorable object the metric
                'metric' belongs to.
              - the context 'ctx' is the context which allows
                the callback to authorize the metric change.
                If the cb method decides not to authorize this
!           particular invocation, it MUST throw an
              'AuthorizationFailed' exception.
              - if no context is available, a context of type
                'Unknown' is passed, with no attributes
                attached. Note that this can also indicate
                that a non-authenticated party connected.
              - a callback can be added to a metric multiple
!           times. A 'false' return value (no keep) will
              remove only one registration, and keep the
              others.
              - a callback can be added to multiple metrics at
                the same time. A false return (no keep) will
                only remove the registration on the metric the
                callback was invoked on.
              - the application must ensure appropriate locking
!           of callback instances which are used with multiple
!           metrics.
              - a callback added to exactly one metric exactly
                once is guaranteed to be active at most once at
!           any given time. That implies that the SAGA
!           implementation MUST queue pending requests
!           until a callback invocation is finished.
```

Class `metric`

The fundamental object introduced in this package is a `metric`. A metric represents an observable *item*, which can be readable, or read/writable. The availability of a readable observable corresponds to monitoring; the availability of a writable observable corresponds to steering. A metric is `Final` when its values cannot change anymore, *ever* (i.e. progress is 100%, job state is `Done` etc).

The approach is severely limited by the use of SAGA attributes for the description of a metric, as these are only defined in terms of string-typed keys and values. An extension of the attribute definition by typed values will greatly improve the usability of this package, but will also challenge its semantic simplicity.

The metric MUST provide access to following attributes (examples given):

<code>name:</code>	short human readable name. - ex: <code>file.copy.progress</code>
<code>desc:</code>	extensive human readable description - ex: "This metric gives the state of an ongoing file transfer as percent completed."
<code>mode:</code>	"ReadOnly", "ReadWrite" or "Final" - ex: "ReadWrite"
<code>unit:</code>	Unit of values - ex: "percent (%)" - ex: "Unit"
<code>type:</code>	"String", "Int", "Enum", "Float", "Bool", "Time", "Trigger" - ex: "Float"
<code>value:</code>	value of the metric - ex: "20.5"

The name of the metric must be unique, as it is used in several methods to identify the metric of interest. The use of a dot-delimited name space for metrics as in the example above is encouraged, as it greatly benefits the interactive handling of metrics. The first element of the name space SHOULD be the SAGA

class the metric belongs to, the second element **SHOULD** be the operation the metric describes (if applicable, otherwise leave out), the third element **SHOULD** indicate the description of the metric (e.g. 'state' or 'progress' or 'temperature'). Illustrative examples for metric names are:

```
file.copy.progress
file.move.progress
file.size
job.state
drive.temperature // a custom observable
```

The name, description, type and mode attributes are **ReadOnly** – so only unit and value can be changed by the application. All attributes are initialized in the metric constructor. The **mode**, **unit** and **value** attributes can be changed internally, i.e. by the SAGA implementation or lower layers. Such a change does cause the metric to *fire*. For example, a metric fires if its **mode** changes from **ReadWrite** to **Final**.

The **name** attribute **MUST** be interpreted case insensitive: An implementation **MAY** change that attribute to *all-lowercase* on metric creation.

If **fire()** is called on a metric, it returns immediately, but any callbacks registered on that metric are not invoked immediately. Instead, the remote entity which is represented by the metric gets invoked first, and only if it acknowledges the changes, the callbacks are invoked. A fire can thus fail in the sense that the remote entity declines the changes. It is good practice to have at least one callback registered on the metric before calling **fire()**, in order to confirm the operation.

The metric **types** are the same as defined for attributes, and the metric **values** are to be formatted as described for the respective attribute types. *The only exception is a metric of type **Trigger** which has no value at all – an attempt to access the value of that metric **MUST** result in a **DoesNotExist** exception.*

Metric definitions in the SAGA specification

The SAGA specification defines a number of metrics which **MUST** or **CAN** be supported, for various SAGA objects. An example **of** such a definition is (from the `saga::stream` object):

```

        class stream ...
        {
            ...

            // Metrics:
!           // name: stream.read
            // desc: fires if a stream gets readable
            // mode: ReadOnly
            // unit: 1
            // type: Trigger
!           // value: 1
            //
            // ...
        }

```

These specifications are **NORMATIVE**, even if described as comments in the SIDL specification! The specified metrics **MUST** be supported by an implementation, unless noted otherwise in the mode description, as:

```

        // mode: ReadOnly, optional
        // mode: ReadWrite, optional

```

If a metric **MUST** be supported, but the SAGA implementation cannot provide that metric, any operation on that metric **MUST** throw a `NotImplemented` exception, and the resulting error message **MUST** state "Metric <name> not not available in this implementation".

Implementations **MAY** add custom metrics, which **SHOULD** be documented similarly. However, metrics **CAN** also be added at runtime – that is, for example, required for computational steering of custom applications.

Metric Lifetime

A metric can *appear* and *go away* during the lifetime of an object (again, computational steering provides the obvious use case for this). Any operation on a metric which got removed (*dead metric*) **MUST** throw an `IncorrectState` exception, *with the exceptions described below*. Existing class instances of a dead metric **MUST** stay valid, and expose the same lifetime as any other *live* metric.

Attributes of a dead metric MUST be readable for the lifetime of the object. The `mode` attribute of such an instance MUST be changed to `Final` by the implementation. **Callbacks** cannot be registered to a `Final` metric, but can be unregistered. No other changes are allowed on a `Final` metric, neither by the user, nor by the SAGA implementation. *Allowed values for mode are `ReadOnly`, `ReadWrite`, and `Final`.*

Client Side Authorization

A metric can get fired from a remote party - in fact, that will be the default situation for both monitoring and steering. In order to allow for client side authorization, **callbacks** get a context as second parameter. That context contains information to be used to authorize the remote party which caused the metric to fire, and the callback to be invoked. Thus, authorization is only available via the callback mechanism. The context information passed to the callback are assumed to be authenticated by the implementation. If no context information **is** available, a context of type `'Unknown'` is passed, which has no attributes attached.

A callback can evaluate the passed context, and throw **an `AuthorizationFailed`** exception if the context (i.e. the remote party) is not deemed trustworthy. See callback description above.

```

- CONSTRUCTOR
  Purpose:  create the object
  Format:   CONSTRUCTOR      (in  string  name
                              in  string  desc,
                              in  string  mode,
                              in  string  unit,
                              in  string  type,
                              in  string  value,
                              out metric  obj);
!   Inputs:  name:           name of the metric
!             desc:          description of the metric
!             mode:          mode of the metric
!             unit:          unit of the metric value
!             type:          type of the metric
!             value:         initial value of the metric
+   InOuts:  -
+   Outputs: obj:            the newly created object
+   PreCond: -
+   PostCond: - callbacks can be registered on the metric.
+   Perms:   -

```

```

    Throws:  NotImplemented
             BadParameter
             Timeout
             NoSuccess

    Notes:   - a metric is not attached to a session, but
              can be used in different sessions.
              - the string arguments given are used to
              initialize the attributes of the metric.
!              , which
-              are subsequently ReadOnly (see description
-              above).
              - the constructor ensures that metrics are
              always initialized completely. All changes to
              attributes later will always result in an
              equally valid metric.
              - incorrectly formatted 'value' parameter,
              invalid 'mode' and 'type' parameter, and empty
              required parameter (all but 'unit') will cause
              a 'BadParameter' exception.
              - a 'Timeout' or 'NoSuccess' exception indicates
              that the backend could not create that specific
              metric.

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR          (in metric obj)
  Inputs:   obj:                the object to destroy
+  InOuts:  -
+  Outputs: -
+  PreCond: -
+  PostCond: - all callbacks registered on the metric are
!              unregistered.
+  Perms:   -
+  Throws:  -
+  Notes:   - if a callback is active at the time of
!              destruction, the destructor MUST block until
!              that callback returns. The callback is not
!              activated anew during or after that block.

// manage callbacks on the metric
- add_callback
!  Purpose:  add asynchronous notifier callback to watch
             metric changes
             Format:  add_callback          (in callback cb,

```

```

                                out int      cookie);
                                callback class instance
+   Inputs:   cb:
+   InOuts:   -
+   Outputs:  cookie:          handle for this callback,
                                to be used for removal
+   PreCond:  - the metric is not 'Final'.
+   PostCond: - the callback is invoked on metric changes.
+   Perms:    Read
+   Throws:   NotImplemented
-             WriteOnly
             IncorrectState
             PermissionDenied
             AuthorizationFailed
             AuthenticationFailed
             Timeout
             NoSuccess
Notes:        - 'IncorrectState' is thrown if the metric is
               'Final'.
               - the 'callback' method on cb will be invoked on
                 any change of the metric (not only when its
                 value changes)
               - if the 'callback' method returns true, the
                 callback is kept registered; if it returns
                 false, the callback is called, and is
                 un-registered after completion. If the
                 callback throws an exception, it stays
                 registered.
               - the cb is passed by reference.
               - the returned cookie uniquely identifies the
                 callback, and can be used to remove it.
!           - A 'Timeout' or 'NoSuccess' exception is thrown
!           if the implementation cannot invoke the
!           callback on metric changes.
               - a backend MAY limit the ability to add
                 callbacks - the method may hence cause an
                 'AuthenticationFailed', 'AuthorizationFailed'
                 or 'PermissionDenied' exception to be thrown.

- remove_callback
  Purpose:  remove a callback from a metric
-           changes
  Format:   remove_callback    (in int      cookie);
  Inputs:   cookie:           handle identifying the cb to
                                be removed
+   InOuts:  -

```

```

        Outputs: -
+       PreCond: - the callback identified by 'cookie' is
+                 registered for that metric.
+       PostCond: - the callback identified by 'cookie' is not
+                 active, nor invoked ever again.
+       Perms:    Read
+       Throws:   NotImplemented
+                 BadParameter
-                 WriteOnly
+                 PermissionDenied
+                 AuthorizationFailed
+                 AuthenticationFailed
+                 Timeout
+                 NoSuccess
+       Notes:    - if a callback is active at the time of
+                 removal, the call MUST block until
+                 that callback returns. The callback is not
+                 activated anew during or after that block.
+                 - if the callback was removed earlier, or
+                   was unregistered by returning false, this call
+                   does nothing.
+                 - the removal only affects the cb identified
+                   by 'cookie', even if the same callback was
+                   registered multiple times.
+                 - if the cookie was not created by adding a
+                   callback to this object instance, a
+                   'BadParameter' is thrown.
+                 - a 'Timeout' or 'NoSuccess' exception is thrown
+                   if the backend cannot guarantee that the
+                   callback gets successfully removed.
+                 - note that the backend MUST allow the removal of
+                   the callback, if it did allow its addition -
+                   hence, no authentication, authorization or
+                   permission faults are to be expected.
!
- fire
  Purpose: push a new metric value to the backend
  Format:  fire                (void);
  Inputs:  -
+  InOuts: -
  Outputs: -
+  PreCond: - the metric is not 'Final'.
+           - the metric is 'ReadWrite'
+  PostCond: - callbacks registered on the metric are
+           invoked.

```

```

+   Perms:    Write
      Throws:  NotImplemented
-   ReadOnly
      IncorrectState
      PermissionDenied
      AuthorizationFailed
      AuthenticationFailed
      Timeout
      NoSuccess
      Notes:
        - 'IncorrectState' is thrown if the metric is
          'Final'.
        - 'PermissionDenied' is thrown if the metric is
!       not 'ReadWrite' -- That also holds for a once
!       writable metric which was flagged 'Final'.
!       To catch race conditions on this exceptions,
!       the application should try/catch the fire().
        - it is not necessary to change the value of a
          metric in order to fire it.
        - 'set_attribute ("value", "...") on a metric
!       does NOT imply a fire. Hence the value can be
!       changed multiple times, but unless fire() is
!       explicitly called, no consumer will notice.
        - if the application invoking fire() has
          callbacks registered on the metric, these
!       callbacks are invoked.
        - 'AuthenticationFailed', 'AuthorizationFailed'
          or 'PermissionDenied' may get thrown if the
          current session is not allowed to fire this
          metric.
        - a 'Timeout' or 'NoSuccess' exception signals
          that the implementation could not communicate
          the new metric state to the backend.

```

Interface monitorable

The monitorable interface is implemented by those SAGA objects which can be monitored, i.e. which have one or more associated metrics. The interface allows introspection of these metrics, and allows to add callbacks to these metrics which get called if these metrics change.

Several methods of this interface reflect similar methods on the metric class – the additional string argument **name** identifies the metric these methods act upon. The semantics of these calls are identical to the specification above.

```

    // introspection
    - list_metrics
      Purpose: list all metrics associated with the object
      Format:  list_metrics      (out array<string>  names);
      Inputs:  -
    + InOuts:  -
      Outputs: names:           array of names identifying
                                the metrics associated with
                                the object instance

    + PreCond: -
    + PostCond: -
    + Perms:   Query
      Throws:  NotImplemented
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess

      Notes:   - several SAGA objects are required to expose
                certain metrics (e.g. 'task.state'). However,
                in general that assumption cannot be made, as
                implementations might be unable to provide
                metrics. In particular, listed metrics might
    !          actually be unavailable.
              - no order is implied on the returned array
              - the returned array is guaranteed to have no
                double entries (names are unique)
              - an 'AuthenticationFailed',
                'AuthorizationFailed' or 'PermissionDenied'
                exception indicates that the current session
                is not allowed to list the available metrics.
              - a 'Timeout' or 'NoSuccess' exception indicates
                that the backend was not able to list the
                available metrics.

    - get_metric
      Purpose: returns a metric instance, identified by name
      Format:  get_metric      (in  string  name,
                                out metric  metric);
      Inputs:  name:           name of the metric to be
                                returned
    + InOuts:  -
      Outputs: metric:         metric instance identified

```

```

                                by name
+   PreCond:  -
+   PostCond: -
+   Perms:    Query
+   Throws:   NotImplemented
              DoesNotExist
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
+   Notes:    - multiple calls of this method with the same
              value for name return multiple identical
              instances (copies) of the metric.
              - a 'DoesNotExist' exception indicates that the
              backend does not know the metric with the
              given name.
              - an 'AuthenticationFailed',
                'AuthorizationFailed' or 'PermissionDenied'
                exception indicates that the current session
                is not allowed to obtain the named metric.
              - a 'Timeout' or 'NoSuccess' exception indicates
                that the backend was not able to return the
                named metric.

// callback handling
- add_callback
  Purpose: add a callback to the specified metric
  Format:  add_callback      (in string      name,
                             in callback    cb,
                             out int        cookie);
!   Inputs: name:            identifies the metric to
                             which cb
                             is to be added
-           cb:              reference of callback class
+           cb:              reference to callback class
                             instance to be registered
+   InOuts:  -
+   Outputs: cookie:         handle for callback removal
+   PreCond: -
+   PostCond: - the callback is registered on the metric.
+   Perms:   Read on the metric.
+   Throws:  NotImplemented
              DoesNotExist
              IncorrectState

```

```

        PermissionDenied
        AuthorizationFailed
        AuthenticationFailed
        Timeout
        NoSuccess
        NoSuccess
Notes:    - notes to the add_callback method of the metric
           class apply.

- remove_callback
  Purpose: remove a callback from the specified metric
  Format:  remove_callback    (in string name,
                               in int  cookie);
  Inputs:  name:              identifies the metric for
!          cookie:            which cb is to be removed
                               identifies the cb to be
                               removed
+  InOuts:  -
+  Outputs: -
+  PreCond: - the callback was registered on the metric.
+  PostCond: -
+  Perms:   Read on the metric.
  Throws:   NotImplemented
            BadParameter
            DoesNotExist
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
Notes:    - notes to the remove_callback method of the
           metric class apply

```

Interface steerable

The steerable interface is implemented by saga objects which can be steered, i.e. which have writable metrics, and which might allow to add new metrics. Steerable objects *must* also implement the monitorable interface. |

The method `add_metric()` allows to implement steerable applications. In particular, the `saga::self` object is steerable, and allows to add metrics (see description of `saga::self` in the specification of the SAGA job management).

```

// metric handling
- add_metric
  Purpose: add a metric instance to the application
           instance
  Format:  add_metric      (in metric metric,
                           out bool  success);
  Inputs:  metric:        metric to be added
+ InOuts:  -
+ Outputs: success:        indicates success
+ PreCond: -
+ PostCond: - the metric can be accessed from this
+             application, and possibly from other
+             applications.
+ Perms:   Write
+ Throws:  NotImplemented
+           AlreadyExists
-           ReadOnly
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
  Notes:   - a metric is uniquely identified by its name
           attribute - no two metrics with the same name
           can be added.
           - any callbacks already registered on the metric
!          stay registered (the state of metric is not
           changed)
!          - an object being steerable does not guarantee
           that a metric can in fact be added -- the
           returned boolean indicates if that particular
           metric could be added.
           - an 'AuthenticationFailed',
             'AuthorizationFailed' or 'PermissionDenied'
             exception indicates that the current session
             is not allowed to add metrics to the
             steerable.
           - a 'Timeout' or 'NoSuccess' exception indicates
             that the backend was not able to add the
             metric.
           - if a metric with the same name is already
             known for the object, an 'AlreadyExists'
             exception is thrown.

```

```

- if the steerable instance does not support the
  addition of new metrics, i.e. if only the
  default metrics can be steered, an
!   'IncorrectState' exception is thrown.

- remove_metric
  Purpose:  remove a metric instance
  Format:   remove_metric      (in string name);
  Inputs:   name:              identifies the metric to be
                                removed
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - all callbacks registered on that metric are
+               unregistered.
+               - the metric is not available anymore.
+   Perms:   Write
+   Throws:  NotImplemented
+               DoesNotExist
-               ReadOnly
+               IncorrectState
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
  Notes:    - only previously added metrics can be removed;
!             default metrics (saga defined or implementation
!             specific) cannot be removed; attempts to do so
              raise a BadParameter exception.
-             an 'AuthenticationFailed',
              'AuthorizationFailed' or 'PermissionDenied'
              exception indicates that the current session
              is not allowed to remove the metrics from the
              steerable.
-             a 'Timeout' or 'NoSuccess' exception indicates
              that the backend was not able to remove the
              metric.
-             if a metric with that name is not known for
              the object, a 'DoesNotExist' exception is
              thrown.
-             if a steerable instance does not support the
              removal of some metric, e.g. if a metric
              needs to be always present, an
!             'IncorrectState' exception is thrown.

```

For example, the 'state' metric on a steerable job cannot be removed.

```

- fire_metric
  Purpose: push a new metric value to the backend
  Format:  fire_metric      (int string name);
  Inputs:  name:           identifies the metric to be
                        fired
+  InOuts:  -
+  Outputs: -
+  PreCond: -
+  PostCond: -
+  Perms:   Write
+  Throws:  NotImplemented
            DoesNotExist
-          ReadOnly
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
  Notes:   - notes to the fire method of the metric
            class apply
            - fire can be called for metrics which have been
              added with add_metric(), and for predefined
              metrics
            - an 'AuthenticationFailed',
              'AuthorizationFailed' or 'PermissionDenied'
              exception indicates that the current session
              is not allowed to fire the metric.
            - a 'Timeout' or 'NoSuccess' exception indicates
              that the backend was not able to fire the
              metric.
            - if a metric with that name is not known for
              the object, a 'DoesNotExist' exception
              is thrown.
!         - an attempt to fire a metric which is
!         'ReadOnly' results in an 'IncorrectState'
            exception.
            - an attempt to fire a 'Final' metric results in
!         an 'IncorrectState' exception.

```

3.9.3 Examples

Code Example

```
1  callback example: trace all job state changes:
2  -----
3
4  // c++ example
5  // callback definition
6  class trace_cb : public saga::callback
7  {
8      public:
9          bool cb (saga::monitorable mt,
10                 saga::metric      m,
11                 saga::context      c)
12      {
13          std::cout << "metric " << m.get_attribute ("name")
14                   << " fired." << std::endl;
15          return true; // stay registered
16      }
17  }
18
19  // the application
20  int main ()
21  {
22      ...
23
24      // if the callback defined above is added to all known
25      // metrics of all saga objects, a continous trace of state
26      // changes of these saga objects will be written to stdout
27      trace_cb cb;
28
29      saga::job j = ...
30
31      j.add_callback ("state", cb);
32
33      ...
34  }
35
36
37  monitoring example: monitor a write task
38  -----
39
40  // c++ example for task state monitoring
41  class write_metric_cb : public saga::callback
42  {
43      public:
44          bool cb (saga::monitorable mt,
45                 saga::metric      m,
46                 saga::context      c)
```

```

47     {
48         saga::task t = saga::task (mt);
49
50         std::cout << "bytes written: "
51                     << m.get_attribute ("value")
52                     << std::endl;
53         std::cout << "task state:  "
54                     << t.get_state ()
55                     << std::endl;
56
57         return true; // keep callback registered
58     }
59 };
60
61 int main (int argc, char** argv)
62 {
63     ssize_t      len = 0;
64     saga::buffer buf ("Hello SAGA\n");
65     saga::url     url (argv[1]);
66
67     saga::file    f (url);
68     saga::task    t = f.write <saga::task::Async> (buf, &len);
69
70     // assume that a file write task has a 'progress' metric
71     // indicating the number of bytes already written.  In
72     // general, the list of metric names has to be searched
73     // for an interesting metric, unless it is a default
74     // metric as specified in the SAGA spec.
75
76     // create and add the callback instance
77     write_metric_callback cb;
78     t.add_callback ("file.write.progress", cb);
79
80     // wait until task is done, and give cb chance to get
81     // called a couple of times
82     t.wait ();
83 }
84
85
86 steering example: steer a remote job
87 -----
88
89 // c++ example
90 class observer_cb : public saga::metric::callback
91 {
92     public:
93         bool cb (saga::monitorable mt,
94                 saga::metric      m,
95                 saga::context      c)
96     {

```

```
97         std::cout << "the new value is"
98         << atoi ( m.get_attribute ("value") )
99         << std::endl;
100
101         return true; // keep callback registered
102     }
103 };
104
105 // the steering application
106 int main (int argc, char** argv)
107 {
108     saga::job_service js;
109
110     saga::job j = js.run ("remote.host.net",
111                          "my_remote_application");
112
113     // Assume that job has a 'param_1' metric representing
114     // an integer parameter for the remote application.
115     // In general, one has to list the metrics available on
116     // job, with list_metric, and search for an interesting
117     // metric. However, we assume here that we know that
118     // metric exists. So we get that metric, and add an
119     // observer callback to it - that causes the asynchronous
120     // printout of any changes to the value of that metric.
121
122     // then we get the metric for active steering
123     saga::metric m = j.get_metric ("param_1");
124
125     observer_cb cb;
126     m.add_callback (cb);
127
128     for ( int i = 0; i < 10; i++ )
129     {
130         // if param_1 is ReadOnly, set_value() would throw
131         // 'ReadOnly' - it would not be usable for
132         // steering then.
133         m.set_attribute ("value", std::string (i));
134
135         // push the pending change out to the receiver
136         m.fire ();
137
138         // callback should get called NOW + 2*latency
139         // That means fire REQUESTS the value change, but only
140         // the remote job can CHANGE the value - that change
141         // needs then reporting back to us.
142
143         // give steered application some time to react
144         sleep (1);
145     }
146 }
```

```
147
148
149
150 steering example: BE a steerable job
151 -----
152
153 // c++ example
154 //
155 // the example shows a job which
156 // - creates a metric to expose a Float steerable
157 //   parameter
158 // - on each change of that parameter computes a
159 //   new isosurface
160 //
161 // callback - on any change of the metric value, e.g. due to
162 // steering from a remote GUI application, a new iso surface
163 // is computed
164 class my_cb : public saga::callback
165 {
166     public:
167         // the callback gets called on any steering events, i.e.
168         // if some other application steeres 'me'.
169         bool cb (saga::monitorable mt,
170                 saga::metric      m,
171                 saga::context      c)
172         {
173             // get the new iso-value
174             float iso = atof (m.get_attribute ("value"));
175
176             // compute an isosurface with that iso-value
177             compute_iso (iso);
178
179             // keep this callback alive, and get called again on
180             // the next metric event.
181             return true;
182         }
183     }
184
185 int main ()
186 {
187     // create a metric for the iso-value of an isosurfacers
188     saga::metric m ("application.isosurfacers.isovalue",
189                    "iso-value of the isosurfacers",
190                    "ReadWrite", // is steerable
191                    "",          // no unit
192                    "Float",     // data type
193                    "1.0");      // initial value
194
195     // add the callback which reacts on changes of the
196     // metric's value (returned cookie is ignored)
```

```
197     my_cb cb;
198     m.add_callback (cb);
199
200     // get job handle for myself
201     saga::self self;
202
203     // add metric to myself
204     self.add_metric (m);
205
206     /*
207     // the callback could also have been added with:
208     self.add_callback ("application.isosurfacers.isovalue", cb);
209     */
210
211     // now others can 'see' the metric, e.g. via
212     // job.list_metrics ();
213
214     // compute isosurfaces for the next 10 minutes -
215     // the real work is done in the callback, on incoming
216     // requests (i.e. steering events).
217     sleep (600);
218
219     // on object (self) destruction, metrics and callback
220     // objects are destroyed as well
221     return (0);
222 }
223
224
225
226 monitoring example: callback for stream connects
227 -----
228
229 // c++ example
230 //
231 // callback class which accepts an incoming client
232 // connection, and then un-registers itself. So, it
233 // accepts exactly one client, and needs to be re-registered
234 // to accept another client.
235 class my_cb : public saga::callback
236 {
237     privat:
238         // we keep a stream server and a single client stream
239         saga::stream_server ss_;
240         saga::stream s_;
241
242
243     public:
244         // constructor initializes these (note that the
245         // client stream should not be connected at this
246         // point)
```

```
247     my_cb (saga::stream_server ss,
248             saga::stream      s )
249     {
250         ss_ = ss;
251         s_  = s;
252     }
253
254
255     // the callback gets called on any incoming client
256     // connection
257     bool cb (saga::monitorable mt,
258             saga::metric      m,
259             saga::context      c)
260     {
261         // the stream server got an event triggered, and
262         // should be able to create a client socket now.
263         s_ = ss_.wait ();
264
265         if ( s_.state == saga::stream::Open )
266         {
267             // have a client stream, we are done
268             // don't call this cb again!
269             return (true);
270         }
271
272         // no valid client stream obtained: keep this
273         // callback alive, and get called again on the
274         // next event on ss_
275         return true;
276     }
277 }
278
279 int main ()
280 {
281     // create a stream server, and an un-connected
282     // stream
283     saga::stream_server ss;
284     saga::stream      s;
285
286     // give both to our callback class, and register that
287     // callback with the 'client_connect' metric of the
288     // server. That causes the callback to be invoked on
289     // every change of that metric, i.e. on every event
290     // that changes that metric, i.e. on every client
291     // connect attempt.
292     my_cb cb (ss, s);
293     ss.add_callback ("client_connect", cb);
294
295     // now we serve incoming clients forever
296     while ( true )
```

```
297     {
298         // check if a new client is connected
299         // the stream state would then be Open
300         if ( s.state == saga::stream::Open )
301         {
302             // a client got conncted!
303             // handle open socket
304             saga::buffer buf ("You say hello, "
305                             "I say good bye!\r\n", 33);
306             s.write (buf);
307
308             // and close stream
309             s.close ();
310
311             // the stream is not Open anymore. We re-add the
312             // callback, and hence wait for the next client
313             // to connect.
314             ss.add_callback ("client_connect", cb);
315         }
316         else
317         {
318             // no client yet, idle, or do something useful
319             sleep (1);
320         }
321     }
322
323     // we should never get here
324     return (-1);
325 }
```

3.10 SAGA Task Model

Operations performed in highly heterogenous distributed environments may take a long time to complete, and it is thus desirable to have the ability to perform operations in an asynchronous manner. The SAGA task model as described here, provides this ability to all other SAGA classes. As such, the package is orthogonal to the rest of the SAGA API.

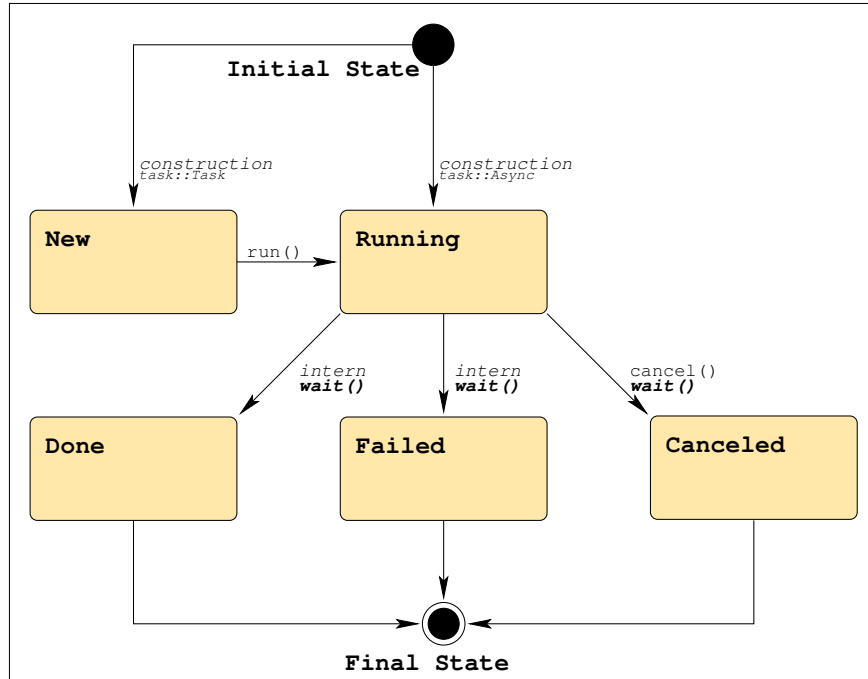

Figure 3: The SAGA task state model (See figure 1 for a [legend](#)).

In order to understand the SAGA task model it is *not* sufficient to read the specification of the `saga::task` and `saga::task_container` classes below, but it is also imperative to understand how task instances get created. This is actually not covered in the SIDL specification sections in this document, but documented in prose below, with references to Figure 3. Note that the task state model is closely modeled after the BES state model [12], which is in particular relevant to the (similar) job state model as described in Section 4.1.

Tasks versus Jobs

In SAGA, tasks should not be confused with jobs! Jobs represent remotely running applications/executables, which are usually managed by a job manager. Tasks on the other hand represent asynchronous operations. Thus, any asynchronous method call in SAGA results in a task.

*Tasks and jobs have, however, several commonalities, the most important one is state: both can be newly created (in **New** state), can be currently making progress (in **Running** state), or can be finished in some way (in **Done**, **Failed** or **Canceled** state). Additionally, jobs can be suspended and resumed (they have a **Suspended** state).*

Mostly for this reason, and to simplify the management of both tasks and jobs in SAGA, the `saga::job` class inherits the `saga::task` class.

Tasks versus Threads

Tasks and threads are another potential pair to confuse: in many APIs and programming languages, tasks and asynchronous operations are implemented by threading. In SAGA, however, tasks have a semantically richer meaning. In particular, threads always imply that the state management for the asynchronous operation lies within the application hosting the thread. SAGA tasks, however, imply no such restriction.

For example, a SAGA task to copy a remote file could be implemented by using the Globus Reliable File Transfer Service (RFT, [1]): the asynchronous method invocation in SAGA would then start the remote operation on the RFT service. All management of the operation progress is in the service - no threading at all is required on the application side. Even more: the application could finish, and after restart could reconnect to the RFT service, and recreate the task, as the complete state is still available on the RFT service - that is basically impossible with threads. Well, it is also not possible in SAGA right now, but for very different reasons, and it is expected that future versions and extensions of SAGA add this and other options to the notion of tasks.

*Implementors of SAGA are warned **not** to rely solely on threading while implementing `saga::task`, but to exploit middleware support for server side asynchronous operations wherever possible.*

Task Model Description

The SAGA task model operates as follows:

- A SAGA object is said to *implement the SAGA task model* if, (a) it inherits the `saga::async` interface, and (b) all methods on that object are implemented in three different versions, which are called *synchronous*, *asynchronous*, and *task* version.
- The *synchronous* version of a SAGA call **corresponds** to the normal method call specified in the SAGA specification. The first `out` parameter specified (if any) is used as return value.
- The *asynchronous* version of *SAGA* a *SAGA* call has *a different the same* signature, *but returns* a `saga::task` instance. That returned task is in **Running** state and represents the asynchronous operation: it can be queried for state, and can be canceled.
- The *task* version of the SAGA call is very similar to the asynchronous version; the only difference is that the returned task instance is in the **New** state, and must be `run()` to get into the **Running** state.
- For symmetry, a language binding MAY add a second flavour of the synchronous call, which has the same signature as **the** asynchronous and task version, but the returned task is in a final state (i.e., `run()` and `wait()` have been called on that task before returning).²
- *The first out parameter, which is the return value in the synchronous method version, is, in the task and asynchronous version, accessed by calling `task.get_result <return_type> (void);`, which is a templetized member method. That call implies a call to `wait()`. For language bindings where templetized member functions are not available, a language specific mechanism MUST be found, which MAY use type casting.*
- *Other out and all inout parameter for asynchronous operations are passed by reference to the initial function call, and MUST NOT be accessed before the corresponding task enters the Done state. In all other states, no assumption can be made about the contents of these parameters. They are guaranteed to not be accessed or changed by the implementation when the task enters any final state.*
- *in parameters are passed by value, and are assumed to be constant. They can be accessed and changed again as soon as the task instance is created.*
- *The original object instance, from which the task was created, can be retrieved from a task by calling `get_object <object_type> (void);`, again a templetized member method, on the task. The same comments as above apply to that templetized method.*

²Note that state transitions for this type of method call are not shown in the state diagram – the diagram would essentially have 'Done' as **an** initial and final state.

Asynchronous Object Construction

The task model as described above focuses on asynchronous invocation of object methods. It does not explicitly cover asynchronous object construction or destruction though. That is important, however, as many constructors, such as for example for `saga::file`, imply a remote operation during construction or destruction (here `open()/close()`).

How asynchronous constructors and destructors are provided is up to the specific language bindings. Procedural bindings, such as expected for C, SHOULD integrate asynchronous versions for the respective method calls to keep these mechanisms in sync with the task model presented above. Object oriented language bindings MAY either introduce an asynchronous factory pattern, or introduce delayed construction/destruction by explicitly using asynchronous `init()` and `close()`, or MAY introduce some other mechanism which most natively allows to asynchronously create SAGA objects.

Tasks and Error Handling

Errors arising from synchronous method invocations on SAGA objects are, in general, flagged by exceptions, and can be inspected using the `error_handler` interface that all SAGA objects implement. For asynchronous operations, this mechanism would break, as the `error_handler` interface allows *in general* only inspection of the *last* method call – but the order of execution is undefined for asynchronous operations. Additionally, exceptions from asynchronous operations would be difficult to catch, as they would presumably be thrown outside of an exception protection block.

For *this* reason, errors on asynchronous operations (i.e. tasks) are handled as follows:

Error Handler: The `saga::task` class implements the `saga::error_handler` interface, which allows inspection of an error thrown by an asynchronous operation. Errors MUST NOT be reported unless the task enters a final state.

Exceptions: The task instance MUST catch all SAGA exceptions and, if possible, all other exceptions thrown by the asynchronous operation. If an exception is caught by the task instance, the task state MUST be changed to **Failed** immediately. Such exceptions are to be re-thrown by the task when the `rethrow()` method is called.

This specification assumes that tasks are, in general, created and maintained in the API implementation, and not in the backend. However, for those cases

where task states are maintained in the middleware backend, several methods on `tasks` and `task_containers` MAY throw a `Timeout` or `NoSuccess` exception, if that backend is not available – *these exceptions can be directly delivered to the application*. It is, however, not allowed to throw an `AuthorizationFailed`, `AuthenticationFailed` or `PermissionDenied` exception, as this **specification** assumes that the creator of the task can always inspect and control that task – *these exceptions MUST be caught, and MUST be made available via `rethrow()`*. Later versions of this API MAY change that, for example when they introduce persistent tasks which can survive the lifetime of a SAGA application.

3.10.1 Example Rendering in C++

Below is an example of how the SAGA task model might be rendered in C++ (this example is not normative). Note that template-tags are used here to distinguish the three task-returning method calls.

Code Example

```

1  // c++ example
2
3  // SAGA specification:
4  // read      (inout array<byte>      buffer,
5  //           in    int                len_in = -1,
6  //           out   int                len_out);
7
8  // create a saga file
9  saga::file f (url);
10
11 // synchronous version
12 ssize_t len_out = f.read (size_t len_in,
13                          char * buffer);
14
15
16 // alternative synchronous version
17 saga::task t1 = f.read <saga::task::Sync>
18                  (size_t len_in,
19                  char * buffer);
20
21 // asynchronous version
22 saga::task t2 = f.read <saga::task::ASync>
23                  (size_t len_in,
24                  char * buffer);
25
26 // asynchronous version
27 // task version
28 saga::task t3 = f.read <saga::task::Task>
29                  (size_t len_in,
30                  char * buffer);

```

```

31
32 // t1 is in Done or Failed state
33 // t2 is in Running state
34 // t3 is in New state
35
36 // get results
37 ssize_t len_out_1 = t1.get_result <ssize_t> ();
38 ssize_t len_out_2 = t2.get_result <ssize_t> ();
39 ssize_t len_out_3 = t3.get_result <ssize_t> ();
40
41 // all tasks are in a final state now,
42 // as get_result() implies a wait().
43
44 // obtain the original file object, three
45 // times the same actually
46 saga::file f1 = t1.get_object <saga::file> ();
47 saga::file f2 = t2.get_object <saga::file> ();
48 saga::file f3 = t3.get_object <saga::file> ();

```

A C language binding of this package might choose to use flags to distinguish *between* these calls; equivalently the C binding might use different method names, for it is up to the language bindings to define the mechanism that is native – or as close as possible – to the language to distinguish these calls.

Note that a SAGA task represents an asynchronous version of a SAGA API method call, and as such it may, or may not have a one-to-one correspondence to an external process, thread, or operation handle.

In general, care should be exercised not to confuse tasks and jobs, as they represent different paradigms: a SAGA job explicitly and always represents an externally running executable, performing any kind of work and as such IS-A task; whereas the internal representation of a SAGA task is very much up to the implementation, and a task is not always a job, i.e. is not always performed by running an executable.

It should also be noted that the task state model (see Fig. 3) and the job state model (see Fig. 4) are very similar, in that the task states represent a subset of the job state model (as can be expected, for a job IS-A task).

For additional notes on resource management and task lifetime, see the introduction Section 2.5.3 of this document.

3.10.2 Specification

```

package saga.task
{
    enum state

```

```
{
    New      = 1,
    Running  = 2,
    Done     = 3,
    Canceled = 4,
    Failed   = 5
}

enum wait_mode
{
    All      = 0,
    Any      = 1
}

interface async
{
    // this interface is empty on purpose, and is used only
    // for tagging of SAGA classes which implement the SAGA
    // task model.
}

class task : implements saga::object
            implements saga::monitorable
            // from object saga::error_handler
{
!   // no constructor
    DESSTRUCTOR      (in task      obj);

+   // state management
    run              (void);
    cancel            (in float      timeout = 0.0);
    wait              (in float      timeout = -1.0,
                      out boolean    finished);

+   // inspection
    get_state         (out state     state);
+   get_result <type> (out type      result);
+   get_object <type> (out type      object);

+   // error handling
    rethrow           (void);

    // Metric:
```

```

        // name: task.state
!       // desc: fires on task state change, and
        //         has the literal value of the task
        //         state enum.
        // mode: ReadOnly
        // unit: 1
!       // type: Enum
        // value: 0
    }

class task_container : implements saga::object
                      implements saga::monitorable
                      // from object saga::error_handler
{
    CONSTRUCTOR      (out task_container obj);
    DESCTRUCTOR      (in task_container obj);

+   // task management
    add              (in task          task,
                     out int          cookie);
    remove           (in int          cookie,
                     out task        task);

    list_tasks       (out array<int>   cookies);
+   get_task         (in int          cookie,
+                   out task        t);
    get_tasks        (out array<task>  tasks);
    get_states       (out array<state> states);

    // Metric:
!   // name: task_container.state
    // desc: fires on state changes of any task in
    //         container, and has the value of that
    //         task's cookie.
    // mode: ReadOnly
    // unit: 1

```

```
    //   type:  Int
    //   value: -
  }
}
```

3.10.3 Specification Details

Enum state

A task can be in one of several possible states (*see Fig. 3*):

New: The task has been created but not yet started. Tasks start in this state, it is initial.

New

This state identifies a newly **constructed** task instance which has not yet run. This state corresponds to the BES state 'Pending'. This state is initial.

Running

The `run()` method has been invoked on the task, either explicitly or implicitly. This state corresponds to the BES state 'Running'. This state is initial.

Done

The synchronous or asynchronous operation has finished successfully. It corresponds to the BES state 'Finished'. This state is final.

Canceled

The asynchronous operation has been canceled, i.e. `cancel()` has been called on the task instance. It corresponds to the BES state 'Canceled'. This state is final.

Failed

The **synchronous** or asynchronous operation has finished unsuccessfully. It corresponds to the BES state 'Failed'. This state is final.

Enum wait_mode

The `wait_mode` enum specifies the condition on which a `wait()` operation on a `saga::task_container` returns:

All

wait() returns if all tasks in the container reached a final state.

Any

wait() returns if one or more tasks in the container reached a final state.

Class task

Objects of this class represent asynchronous API calls. They are only created by invoking a method on a **SAGA** object which returns a task object (with `saga::task::ASync` or `saga::task::Task`). But as `saga::job` instances inherit from the task class, *tasks jobs* are also effectively created as *jobs tasks*.

If a task gets created, it will share the state of the object it was created from. For more information on state sharing, see [Section 2.5.3](#).

Note that no CONSTRUCTOR is available, as tasks are only created through asynchronous method calls.

```

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR           (in task obj)
  Inputs:   obj:                 the object to destroy
+ InOuts:   -
+ Outputs:  -
+ PreCond:  -
+ PostCond: - state is no longer shared with the object
+           the task was created from.
!           - the task instance is 'Canceled' prior to
+           resource deallocation.
+ Perms:    -
+ Throws:   -
+ Notes:    - if the instance was not in a final state
+           before, the destructor performs a cancel()
+           on the instance, and all notes to cancel()
+           apply.

+ State Management
+ -----
+
- run
  Purpose:  Start the asynchronous operation.
```

```

        Format:    run (void);
        Inputs:    -
+       InOuts:    -
        Outputs:    -
+       PreCond:   - task is in 'New' state.
+       PostCond:  - task is in 'Running' state.
+       Perms:     - appropriate permissions for the method
+                   represented by the task
        Throws:    NotImplemented
                   IncorrectState
                   Timeout
                   NoSuccess
        Notes:     - run can only be called on a task in 'New'
                   state. All other states will cause the
                   'IncorrectState' exception to be thrown.
                   - a 'Timeout' or 'NoSuccess' exception indicates
                   that the backend was not able to start the
                   task.

- wait
  Purpose: Wait for the task to finish.
  Format:  wait                               (in float timeout,
                                              out boolean done);
  Inputs:  timeout:                          seconds to wait
+  InOuts:  -
  Outputs:  done:                            indicating if the task
                                              is done running
+  PreCond: - task is not in 'New' state.
+  PostCond: - if no timeout occurs, task is in a final
+              state.
+  Perms:    -
  Throws:    NotImplemented
             IncorrectState
+           Timeout
             NoSuccess
  Notes:     - wait returns success (true) as soon as the
             task enters a final state
             - if the task is already in a final state, the
             call returns success (true) immediately.
             - if the task is in 'New' state, an
             'IncorrectState' exception is thrown.
             - wait returns no success (false) if the task
             is, even after timeout, not in a final state.
             - a 'Timeout' or 'NoSuccess' exception indicates
             that the backend was not able to wait for the

```

```

        task. Note that a 'Timeout' exception does
        not indicate that the task is not in a final
        state after the given wait period - that
        causes an unsuccessful (false) return value.
!         - for timeout semantics, see Section 2.

- cancel
  Purpose: Cancel the asynchronous operation.
  Format:  cancel                (in float timeout);
  Inputs:  timeout:              time for freeing resources
+  InOuts: -
  Outputs: -
+  PreCond: - task is in 'Running' state.
+  PostCond: - task is in 'Canceled' state.
+  Perms:    -
  Throws:    NotImplemented
              IncorrectState
+           Timeout
              NoSuccess
  Notes:     - for resource deallocation semantics, see
!             Section 2.
!             - if cancel() fails to cancel the task
!               immediately, and tries to continue to cancel
               the task in the background, the task state
               remains 'Running' until the cancel operation
               succeeded. The state then changes to
               'Canceled'.
!             - if the task is in a final state, the call has
               no effect, and, in particular, does NOT change
               the state from 'Done' to 'Canceled', or from
               'Failed' to 'Canceled'. This is to
               avoid race conditions.
!             - if the task is in 'New' state, an
               'IncorrectState' exception is thrown.
!             - a 'NoSuccess' exception indicates
               that the backend was not able to initiate the
               cancelation for the task.
!             - for timeout semantics, see Section 2.

+  Inspection
+  -----
+
-  get_state
  Purpose: Get the state of the task.

```

```

        Format:  get_state          (out state state);
        Inputs:  -
+       InOuts:  -
        Outputs: state:              state of the task.
+       PreCond: -
+       PostCond: -
+       Perms:   -
        Throws:  NotImplemented
                Timeout
                NoSuccess
        Notes:   - a 'Timeout' or 'NoSuccess' exception indicates
                  that the backend was not able to retrieve the
                  task state.

+
+ - get_result
+   Purpose:  Get the result of the async operation
+   Format:   get_result <type>    (out type result);
+   Inputs:   -
+   InOuts:   -
+   Outputs:  result:              return value of async
+                                   method
+   PreCond:  - task is not in New, Failed or Canceled state.
+   PostCond: - task is in a final state.
+   Perms:    -
+   Throws:   NotImplemented
+             IncorrectState
+             Timeout
+             NoSuccess
+   Notes:    - get_result implies a wait() - all notes to
+               wait apply.
+               - the method returns the type and value which
+                 would be returned by the synchronous version of
+                 the respective function call.
+
+
+ - get_object
+   Purpose:  Get the object from which this task was created
+   Format:   get_object <type>    (out type object);
+   Inputs:   -
+   InOuts:   -
+   Outputs:  object:              object this task was
+                                   created from
+   PreCond:  -
+   PostCond: -
+   Perms:    -

```

```

+   Throws:   NotImplemented
+             Timeout
+             NoSuccess
+   Notes:    - the method returns a shallow copy of the
+               object this task was created from.
+
-   rethrow
    Purpose:  re-throw any exception a failed task caught.
    Format:   rethrow (void);
    Inputs:   -
+   InOuts:   -
    Outputs:  -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
    Throws:   NotImplemented
-           IncorrectSession
-           IncorrectURL
-           BadParameter
-           AlreadyExists
-           DoesNotExist
-           ReadOnly
-           WriteOnly
-           IncorrectState
-           PermissionDenied
-           AuthorizationFailed
-           AuthenticationFailed
-           Timeout
-           NoSuccess
    Notes:    - that method does nothing unless the task is in
               'Failed' state, and also MUST NOT throw
               'IncorrectState' if the task is in any other
               state.
               - if in 'Failed' state, the method MUST raise an
                 exception which indicates the reason why that
                 task entered the 'Failed' state (i.e. it throws
                 the exception which caused it to enter the
                 'Failed' state.
+               - language bindings for languages with no
+                 support for exceptions MUST change the state
+                 of the object from which the task was created
+                 so that a subsequent call to has_error() on
+                 that object returns true. A subsequent call to
+                 get_error() must then return the respectiv
+                 exception.

```

-
- + - rethrow can be called multiple times, always
 - + throwing the same exception.
-

Class `task_container`

Managing a large number of tasks can be tedious. The `task_container` class is *designed* to help in these situations, and to effectively handle a large number of asynchronous operations.

For example, when *an application uses* many *asynchronous* tasks, it would be inefficient to invoke the `wait()` method on each *of them individually*. The `task_container` class provides (amongst other operations) a mechanism to wait for a set of tasks.

Language bindings CAN specify the `task_container` to be, or to inherit from, a native container type, if that allows for the same semantics as described below, and if that helps to 'naturalize' the SAGA Look & Feel for that language.

- CONSTRUCTOR
 - Purpose: create a `task_container`
 - Format: CONSTRUCTOR (out `task_container` tc);
 - Inputs: -
 - + InOuts: -
 - Outputs: tc: newly created container
 - + PreCond: -
 - + PostCond: -
 - + Perms: -
 - Throws: NotImplemented
 - Timeout
 - NoSuccess
 - Notes: - a 'Timeout' or 'NoSuccess' exception indicates that the backend was not able to create a task container.
 - DESTRUCTOR
 - Purpose: destroy a `task_container`
 - Format: DESTRUCTOR (in `task_container` tc);
 - Inputs: tc: container to destroy
 - + InOuts: -
 - Outputs: -
 - + PreCond: -
 - + PostCond: -
-

```

+   Perms:      -
+   Throws:     -
+   Notes:      - tasks in the task_container during its
                  destruction are not affected by its
                  destruction, and, in particular, are not
                  canceled.

+   Task Management
+   -----

-   add
    Purpose:    Add a task to a task_container.
    Format:     add                (in task task,
+                                     out int cookie);
    Inputs:     task:              task to add to the
                                     task_container
+   InOuts:     -
+   Outputs:    cookie:            cookie identifying the
+                                     added task
+   PreCond:    -
+   PostCond:   - the task is managed by the task container.
+   Perms:      -
+   Throws:     NotImplemented
                  Timeout
                  NoSuccess
!   Notes:      - a task can be added only once. Any attempt
+                 to add a task to the container which already
+                 is in the container is silently ignored, and
+                 the same cookie as for the original task is
+                 returned again.
+                 - a 'Timeout' or 'NoSuccess' exception indicates
+                 that the backend was not able to add the task
+                 to the container.

-   remove
    Purpose:    Remove a task from a task_container.
    Format:     remove            (in int cookie,
+                                     out task task);
    Inputs:     task:            cookie identifying the
                                     task to be removed
+   InOuts:     -
+   Outputs:    task:            the removed task
+   PreCond:    - the task is managed by the task container.
+   PostCond:   - the task is not managed by the task container.

```

```

+   Perms:      -
+   Throws:     NotImplemented
+               DoesNotExist
+               Timeout
+               NoSuccess
!   Notes:      - if a task was added more than once, it can be
!                 removed only once - see notes to add().
!               - if the task identified by the cookie is not in
+                 the task_container, a 'DoesNotExist' exception
+                 is thrown.
+               - a 'Timeout' or 'NoSuccess' exception indicates
+                 that the backend was not able to remove the
+                 task from the container.

+   State Management
+   -----

-   run
    Purpose:    Start all asynchronous operations in the
                container.
    Format:     run (void);
    Inputs:     -
+   InOuts:    -
    Outputs:    -
+   PreCond:   - all tasks in the container are in 'New' state.
+   PostCond:  - all tasks in the container are in 'Running'
+               state.
+   Perms:     - see permissions on task::run()
    Throws:     NotImplemented
+               IncorrectState
+               DoesNotExist
+               Timeout
+               NoSuccess
    Notes:      - run() MUST cause an 'IncorrectState' exception
                if any of the tasks in the container causes
                that exception on run().
                - a 'Timeout' or 'NoSuccess' exception indicates
                that the backend was not able to run one or
                more tasks in the container.
+               - if the task_container is empty, an
+               'DoesNotExist' exception is thrown.
                - As the order of execution of the tasks is
                undefined, no assumption on the individual
                task states can be made after any
                exception gets thrown.

```

```

- wait
  Purpose: Wait for one or more of the tasks to finish.
!   Format: wait (in wait_mode mode = All,
!               in float timeout = -1.0,
!               out task done);
!   Inputs: mode: wait for All or Any task
!           timeout: seconds to wait
+   InOuts: -
+   Outputs: done: finished task
+   PreCond: -
+   PostCond: - if no timeout occurs, All/Any tasks in the
+               container are in a final state.
+   Perms: -
+   Throws: NotImplemented
+           IncorrectState
+           DoesNotExist
+           Timeout
+           NoSuccess
  Notes: - if mode is 'All', the wait call returns only
!         if all tasks in the container are finished,
!         or on timeout, whichever occurs first.
!         The output task is then any of the finished
!         tasks.
!         - if mode is 'Any', the wait call returns on the
!         first task which would return on task::wait in
!         that timeout period, and returns that task.
!         - the default wait mode is 'All' (0).
!         - the returned task is removed from the
!         container, which allows constructs like
!         while ( tc.size () )
!         {
!             saga::task t = tc.wait (saga::task::Any) )
!             ...
!         }
!         - wait() MAY cause an 'IncorrectState' exception
!         if any of the tasks in the container causes
!         that exception on wait().
+         - if the task_container is empty, an
+         'DoesNotExist' exception is thrown.
+         - a 'Timeout' or 'NoSuccess' exception indicates
+         that the backend was not able to wait for one
+         or more tasks in the container.
+         - As the order of execution of the tasks is
+         undefined, no assumption on the individual

```

```

        task states can be made after any
        exception gets thrown.
!      - for timeout semantics, see Section 2.

- cancel
  Purpose: Cancel all the asynchronous operations in the
           container.
  Format:  cancel                               (in float timeout);
  Inputs:  timeout:                             time for freeing resources
+  InOuts: -
+  Outputs: -
+  PreCond: -
+  PostCond: - if no timeout occurs, all tasks in the
+              container are in 'Canceled' state.
+  Perms:    -
!  Throws:   NotImplemented
+           IncorrectState
+           DoesNotExist
+           Timeout
+           NoSuccess
  Notes:    - see semantics of task cancel.
!           - cancel() MUST cause an 'IncorrectState'
!             exception if any of the tasks in the container
!             causes that exception on cancel().
+           - a 'Timeout' or 'NoSuccess' exception indicates
+             that the backend was not able to run one or
+             more tasks in the container.
+           - if the task_container is empty, an
+             'DoesNotExist' exception is thrown.
+           - As the order of execution of the tasks is
              undefined, no assumption on the individual
              task states can be made after any
              exception gets thrown.

+  Inspection
+  -----

+  - size
+  Purpose: return the number of tasks in the task
+           task_container.
+  Format:  size                               (out int n);
+  Inputs:  -
+  InOuts:  -
+  Outputs: n:                                number of tasks in

```

```

+                                     task_container
+   PreCond: -
+   PostCond: -
+   Perms: -
+   Throws:   NotImplemented
+             Timeout
+             NoSuccess
+   Notes:    - a 'Timeout' or 'NoSuccess' exception indicates
+               that the backend was not able to list the
+               tasks in the container.

- list_tasks
!   Purpose:  List the tasks in the task_container.
!   Format:   list_tasks          (out array<int>   cookies);
+   Inputs:   -
+   InOutputs: -
+   Outputs:  cookies:           array of cookies for all
+                               tasks in task_container

+   PreCond: -
+   PostCond: -
+   Perms: -
+   Throws:   NotImplemented
+             Timeout
+             NoSuccess
+   Notes:    - a 'Timeout' or 'NoSuccess' exception indicates
+               that the backend was not able to list the
+               tasks in the container.

+
+ - get_task
+   Purpose:  Get a single task from the task_container.
+   Format:   get_task           (in int      cookie,
+                               out task     t);
+   Inputs:   cookie:           the cookie identifying the
+                               task to return
+   InOutputs: -
+   Outputs:  t:                the task identified by
+                               cookie
+   PreCond: -
+   PostCond: -
+   Perms: -
+   Throws:   NotImplemented
+             DoesNotExist
+             Timeout
+             NoSuccess

```

```

+   Notes:   - the returned task is NOT removed from the
+             task_container.
+             - if cookie specifies a task which is not in the
+             container, a 'DoesNotExist' exception is
+             thrown.
+             - a 'Timeout' or 'NoSuccess' exception indicates
+             that the backend was not able to list the
+             tasks in the container.
+
- get_tasks
!   Purpose:  Get the tasks in the task_container.
Format:      get_tasks          (out array<task>   tasks);
+   Inputs:   -
+   InOuts:   -
Outputs:      tasks:             array of tasks in
                                task_container
+   PreCond:  -
+   PostCond: -
+   Perms:    -
!   Throws:   NotImplemented
+             Timeout
+             NoSuccess
Notes:        - the returned tasks are NOT removed from the
!             task_container.
+             - if the task_container is empty, an
+             empty list is returned.
+             - a 'Timeout' or 'NoSuccess' exception indicates
+             that the backend was not able to list the
+             tasks in the container.

- get_states
!   Purpose:  Get the states of all tasks in the
             task_container.
Format:      get_states          (out array<state>   states);
+   Inputs:   -
+   InOuts:   -
Outputs:      states:             array of states for
                                tasks in task_container
+   PreCond:  -
+   PostCond: -
+   Perms:    -
!   Throws:   NotImplemented
+             Timeout
+             NoSuccess

```

- Notes:
- the returned list is not ordered
 - + - if the task_container is empty, an
 - + empty list is returned.
 - a 'Timeout' or 'NoSuccess' exception indicates that the backend was not able to obtain the states of the tasks in the container.
-

3.10.4 Examples

Code Example

```
1 // c++ example
2 saga::directory dir;
3 saga::job      job;
4
5 ...
6
7 /* create tasks */
8 saga::task t1 = dir.ls      <saga::task> (result);
9 saga::task t2 = dir.copy    <saga::task> (source,target);
10 saga::task t3 = dir.move    <saga::task> (source,target);
11 saga::task t4 = job.checkpoint <saga::task> ();
12 saga::task t5 = job.signal   <saga::task> (SIG_USR);
13
14 // start tasks
15 t1.run ();
16 t2.run ();
17 t3.run ();
18 t4.run ();
19 t5.run ();
20
21 // put all tasks into container
22 saga::task_container tc;
23
24 tc.add (t1);
25 tc.add (t2);
26 tc.add (t3);
27 tc.add (t4);
28 tc.add (t5);
29
30 // take one out again
31 tc.remove (t5);
32
33 // wait for all other tasks in container to finish
34 tc.wait ();
35
36 // wait for the last task
37 t5.wait ();
```

```
38
39 +-----+
40
41 // example for error handling in C++
42 {
43     task.run ();
44     task.wait ();
45
46     if ( task.get_state () == saga::task::Failed )
47     {
48         try {
49             task.rethrow ();
50         }
51         catch ( const saga::exception & e )
52         {
53             std::cout << "task failed: "
54                       << e.get_message ()
55                       << std::endl;
56         }
57     }
58 }
```

4 SAGA API Specification – API Packages

The Functional SAGA API packages define the functional SAGA API scope, as motivated in the [Introduction](#) and in [18].

General Properties of Functional API Classes and Instances

The interfaces, classes and methods defined in this part of the specification are, in general, representing explicit entities and actions of some backend system. As such, all operations on these entities are, in general, subject to [authentication](#) and [authorization](#). In order to simplify the specification, the following exceptions are not separately motivated: `AuthenticationFailed`, `AuthorizationFailed`, `PermissionDenied`, `Timeout`, `NoSuccess`. These exceptions have then exactly the semantics as indicated in their description in Section 3.1. [Additionally](#), the conventions for the exceptions `NotImplemented` and `IncorrectURL` apply as described in Section 3.

4.1 SAGA Job Management

Nearly all of the SAGA use cases (except for the GridRPC use cases) had either explicit or implicit requirements for submitting jobs to grid resources, and most needed to also to monitor and control these submitted jobs.

This section describes the SAGA API for submitting jobs to a grid resource, either in batch mode, or in an interactive mode. It also describes how to control these submitted jobs (e.g. to `cancel()`, `suspend()`, or `signal()` a running job), and how to retrieve status information for both running and completed jobs.

This API is also intended to incorporate the work of the DRMAA-WG [9]. Much of this specification was taken directly from DRMAA specification [24], with many of the differences arising from an attempt to make the job API consistent with the overall SAGA API [Look-&-Feel](#)³.

The API covers four classes: `saga::job_description`, `saga::job_service`, `saga::job` and `saga::job_self`. The job description class is nothing more than a container for a well defined set of attributes which, using JSDL [15] based keys, defines the job to be started, and its *runtime and* resource requirements. The job server represents a resource management endpoint which allows the starting and *insection* of jobs.

The job class itself is central to the API, and represents an application instance running under the management of a resource manager. The `job_self` class IS-A job, but additionally implements the steering interface. The purpose of this class is to represent the current SAGA application, *which* allows for a number of use cases with applications which actively interact with the *grid* infrastructure, for example to provide steering capabilities, to migrate itself, or to set *new* job attributes.

The job class inherits the `saga::task` class 3.10, and uses its methods to `run()`, `wait()` for, and to `cancel()` jobs. The inheritance feature also allows for the management of large numbers of jobs in task containers. Additional methods provided by the `saga::job` class relate to the `Suspended` state (which is not available on tasks), and provide access to the job's standard I/O streams, and to more detailed status information. In this specification, the standard I/O streams are specified to have *opaque* types. The SAGA language bindings MUST specify a native type for I/O streams. That type SHOULD be the one used as the file descriptor to the POSIX `read()` call in that language.

³We expect that SAGA-API implementations may be implemented using DRMAA, or may produce JSDL documents to be passed to underlying scheduling systems.

4.1.1 Job State Model

The SAGA job state diagram is shown in Figure 4. It is an extension of the `saga::task` state diagram (Figure 3), and extends the state diagram with an 'Unknown' state (which is needed for job instances which are not yet initialized, and are to be used for asynchronous initialization), and with a 'Suspended' state, which the job can enter/leave using the `suspend()`/`resume()` calls.

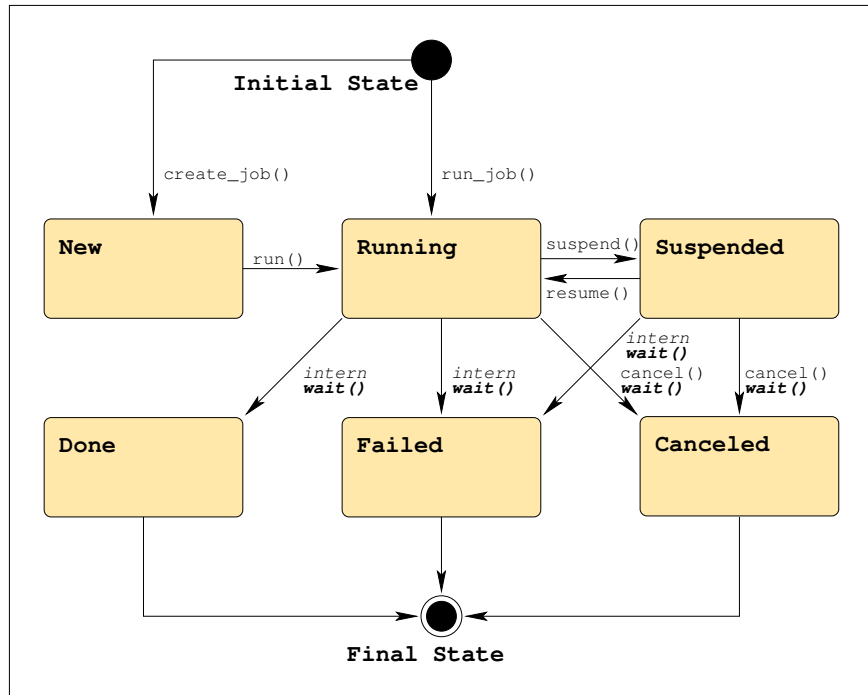

Figure 4: The SAGA job state model extends the SAGA task state model with 'Unknown' and a 'Suspended' state, and additional transitions (See Figure 1 for a legend).

SAGA implementations need to map the native backend state model onto the SAGA state model. The SAGA state model should be simple enough to allow a straight forward mapping in most cases. For some applications, access to the native backend state model is useful. For that reason, an additional metric named 'StateDetail' allows to query the native job state. That schema follows the current state model of the OGSA-BES specification [12], which also has a simplified top level state model, and allows for additional, backend specific state details.

State details in SAGA SHOULD be formatted as follows:

```
'<model>:<state>'
```

with valid models being "BES", "DRMAA", or other implementation specific models. For example, a state detail for the BES state '**StagingIn**' would be rendered as '**BES:StagingIn**'), *and would be a substate of **Running***. If no state details are available, the metric is still available, but it has always an empty string value.

4.1.2 Job Description Attributes

SAGA implementations **MUST** support the **Executable** attribute, as that is the only required attribute for a **job_description**. An implementation **MUST** document which other attributes are supported, and which **are not**. In general, a **job_description** containing an unsupported attribute does *not* cause an error on job creation or submission, unless noted otherwise in the attribute description.

Attributes marked as '**not supported by JSDL**' might disappear in future versions of the SAGA API – all other attributes are likely to be kept, at least for backward compatibility. The attribute description additionally mentions if the attributes are supported by DRMAA (see [24]) – that is for information purposes only, and supposed to support implementations on top of DRMAA.

Several Metrics on the **saga::job** class (the class implements the **saga::monitorable** interface) reflect attributes from the job description. This redundancy is intentional, and aims at providing information about (a) attributes which may change at runtime, and (b) attributes for jobs for which no job description is available (e.g. **saga::job** instances obtained by calling **get.job()**).

Although JSDL [3] *and JSDL SPMD extension [8]* based attribute names are used for job description, the API *supports* no explicit representation of JSDL (i.e. JSDL compliant XML). XML is deemed to be too low level to be included into the SAGA API. *Also, the JSDL parameter sweep extension [7] is not used in SAGA at the moment, as bulk job submission, and related the creation of multiple related job descriptions, is performed on application level in SAGA, as described in section 2.9.*

4.1.3 File Transfer Specifications

The syntax of a file transfer directive for the job description is modeled on the LSF syntax (*LSF stands for Load Sharing Facility, a commercial job scheduler by Platform Computing*), and has the general syntax:

```
local_file operator remote_file
```

Both the **local_file** and the **remote_file** can be URLs. If they are not URLs,

but full or relative pathnames, then the `local_file` is relative to the host where the submission is executed, and the `remote_file` is evaluated on the execution host of the job.

The operator is one of the following four:

- '>' copies the local file to the remote file before the job starts.
Overwrites the remote file if it exists.
- '>>' copies the local file to the remote file before the job starts.
Appends to the remote file if it exists.
- '<' copies the remote file to the local file after the job finishes.
Overwrites the local file if it exists.
- '<<' copies the remote file to the local file after the job finishes.
Appends to the local file if it exists.

4.1.4 Command Line Specification

The `run_job()` method of the `saga::job_service` class accepts a string parameter which constitutes a command line to be executed on a remote resource. The parsing of that command lines follows the following rules:

- **Elements** are delimited by white space, which is either a space or a tab.
- A string surrounded by double quotation marks is interpreted as a single element, regardless of white space contained within. A quoted string can be embedded in an element.
- A double quotation mark preceded by a backslash, `\"`, is interpreted as a literal double quotation mark (`"`).
- Backslashes are interpreted literally, unless they immediately precede a double quotation mark.
- The first **element** is used as executable name; all other elements are treated as job arguments.

4.1.5 Job Identifiers

The **JobID** is treated as an opaque string in the SAGA API. However, for the sake of interoperability of different SAGA implementations, and for potential extended use of the **JobID** information, the **JobID** SHOULD be implemented as:

```
'[backend url]-[native id]'
```

For example, a job submitted to the host `remote.host.net` via `ssh` (whose daemon runs on port 22), and having the *POSIX PID* 1234, should get the job id:

```
'[ssh://remote.host.net:22/]-[1234]'
```

The implementation MAY free the resources used for the job, and hence MAY invalidate a *JobID*, after a successful wait on the job, or after the application *received* the job status information, and job status details if available, at least once.

*A JobID may be unknown until the job enters the **Running** state, as the backend will often not assign IDs to jobs which are not yet running. In such cases, the value of the JobID attribute SHOULD be empty. The job MUST, however, retain its JobID after it enters in a final state.*

4.1.6 Specification

```
package saga.job
{
    enum state
    {
-       Unknown    = -1, // same as in saga::task::state
        New        = 1,  // same as in saga::task::state
        Running    = 2,  // same as in saga::task::state
        Done       = 3,  // same as in saga::task::state
        Canceled   = 4,  // same as in saga::task::state
        Failed     = 5,  // same as in saga::task::state
        Suspended  = 6
    }

    class job_description : implements saga::object
                          implements saga::attributes
                          // from object: saga::error_handler
    {
        CONSTRUCTOR      (out job_description obj);
        DESTRUCTOR        (in  job_description obj);

        // Attributes:
        //   name: Executable
        //   desc: command to execute.
        //   type: String
    }
}
```

```
// mode: ReadWrite
// value: ''
// notes: - this is the only required attribute.
//         - can be a full pathname, or a pathname
//           relative to the 'WorkingDirectory' as
//           evaluated on the execution host.
//         - semantics as defined in JSDL
//         - available in JSDL, DRMAA
//
// name: Arguments
// desc: positional parameters for the command.
// mode: ReadWrite, optional
// type: Vector String
// value: -
// notes: - semantics as specified by JSDL
//         - available in JSDL, DRMAA
//
+ // name: SPMDVariation
+ // desc: SPMD job type and startup mechanism
+ // mode: ReadWrite, optional
+ // type: String
+ // value: -
+ // notes: - as defined in the SPMD extension of JSDL
+ // notes: - semantics as defined in JSDL
+ //         - available in JSDL, SPMD extension
+ //         - the SPMD JSDL extension defines the value
+ //           to be an URI. For simplicity, SAGA allows
+ //           the following strings, which map into the
+ //           respective URIs: MPI, GridMPI, IntelMPI,
+ //           LAM-MPI, MPICH1, MPICH2, MPICH-GM, MPICH-MX,
+ //           MVAPICH, MVAPICH2, OpenMP, POE, PVM, None
+ //         - the value '' (no value, default) indicates
+ //           that the application is not a SPMD
+ //           application.
+ //         - as JSDL, SAGA allows other arbitrary values.
+ //           The implementation must clearly document
+ //           which values are supported.
+ //
// name: TotalCPUCount

        DESTRUCTOR          (in  job_self          obj);
    }
}

```

4.1.7 Specification Details

Enum state

The state is equivalent to the inherited `saga::task::state`, but adds the `Suspended` state:

Suspended

This state identifies a job instance which has been suspended. This state corresponds to the BES state '`Suspend`'.

Class job_description

This object encapsulates all the attributes which define a job to be run. It has no methods of its own, but implements the `saga::attributes` interface in order to provide access to the job properties, which are expressed as JSDL keywords.

The only required attribute in order to perform a valid job submission is the `Executable`. Given the `Executable`, a job can be **instantiated** in many existing backend systems without any further specification.

There should be **significant** overlap between the attributes defined within SAGA and within the JSDL specification. This list, however, will not be complete in cases where the JSDL was deemed more complicated than was required for a simple API (e.g. the notion of JSDL **profiles**), or where an attribute was needed to interact with a scheduler, which was not within the stated scope of the JSDL working group (e.g. `Queue`, which is considered a *site attribute*, and thus not relevant to the pure description of a job).

```

- CONSTRUCTOR
  Purpose:  create the object
  Format:   CONSTRUCTOR          (out job_description obj)
  Inputs:   -
+ InOuts:   -
  Outputs:  obj:                  the newly created object
+ PreCond:  -
+ PostCond: -
+ Perms:    -
  Throws:   NotImplemented
+           NoSuccess
  Notes:    - a job_description is not associated with a
              session, but can be used for job services
              from different sessions.

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR          (in job_description obj)
  Inputs:   obj:                  the object to destroy
+ InOuts:   -
  Outputs:  -
+ PreCond:  -
+ PostCond: -
+ Perms:    -
  Throws:   -
  Notes:    -

```

Class `job_service`

The `job_service` represents a resource management backend, and as such allows to create and submit jobs, and to discover jobs. The job management methods are on the job object itself – **this** probably implies that implementations need to internally track what resource manager (or `job_service` *instance*)

created the job.

```

- CONSTRUCTOR
  Purpose: create the object
  ! Format: CONSTRUCTOR      (in session      s,
  !                               in url        rm = "",
  !                               out job_service obj)
  ! Inputs:  s:              session to associate with
  !                               the object
  !                               rm:          contact url for resource
  !                                       manager
+ InOuts:   -
+ Outputs:  obj:            the newly created object
+ PreCond:  -
+ PostCond: -
+ Perms:    -
+ Throws:   NotImplemented
            IncorrectURL
            DoesNotExist
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
  Notes:    - 'rm' defaults to an empty string - in that
              case, the implementation must perform a
              resource discovery, or fall back to a fixed
              value, or find a valid rm contact in any
              other way. If that is not possible, a
              'BadParameter' exception MUST be thrown, and
              MUST indicate that a rm contact string is
              needed. The expected behaviour MUST be
              documented (i.e. if a default is available).
-           - if the URL's schema cannot be used by the
-           implementation, an 'IncorrectURL' exception
-           is thrown.
-           - if the rm identified by the rm URL cannot be
              contacted (i.e. does not exist), a
              'BadParameter' exception is thrown.

- DESTRUCTOR
  Purpose: destroy the object
  Format:  DESTRUCTOR      (in job_service  obj)

```

```

      Inputs:  obj:          the object to destroy
+      InOuts:  -
      Outputs:  -
+      PreCond:  -
+      PostCond: - jobs created by that job_service instance
+                  are not affected by the destruction, and are
+                  in particular not canceled.
+      Perms:    -
      Throws:    -
      Notes:     -

- create_job
  Purpose: create a job instance
!   Format: create_job      (in job_description jd,
                             out job          job);
!   Inputs:  jd:            description of job to be
                             submitted
+   InOuts:  -
      Outputs: job:          a job object representing
                             the submitted job instance
+   PreCond: - jd has an 'Executable' attribute.
+   PostCond: - job is in 'New' state
+               - jd is deep copied (no state is shared
+               after method invocation)
+               - 'Owner' of the job is the id of the context
+               used for creating the job.
+   Perms:    -
+   Throws:    NotImplemented
+               BadParameter
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
      Notes:    - calling run() on the job will submit it to
+               the resource, and advance its state.
+               - if the job description does not have a valid
+               'Executable' attribute, a 'BadParameter'
+               exception is thrown.
+               - if the job description contains values which
+               are outside of the allowed range, or cannot be
+               parsed, or are otherwise invalid and not
+               usable for creating a job instance, a
+               'BadParameter' exception is thrown, which MUST
!               indicate which attribute(s) caused this

```

exception, and why.

```

- run_job
  Purpose: Run a command synchronously.
!   Format: run_job      (in string  cmdline,
!                        in string  host = "",
!                        out job     job,
!                        out opaque  stdin,
!                        out opaque  stdout,
!                        out opaque  stderr);
!   Inputs:  cmdline:    the command and arguments
!              to be run
!              host:      hostname to be used by rm for
!              submission
+   InOuts:  -
  Outputs:  stdin:       IO handle for the running
!                        job's standard input stream
!                        stdout:      IO handle for the running
!                        job's standard output
!                        stderr:      IO handle for the running
!                        job's standard error
!                        job:         a job object representing
!                        the submitted job instance
+   PreCond: -
+   PostCond: - job is in 'Running', 'Done' or 'Failed' state.
+               - 'Owner' of the job is the id of the context
+               used for creating the job.
+   Perms:    -
  Throws:     NotImplemented
!             BadParameter
!             IncorrectState
!             PermissionDenied
!             AuthorizationFailed
!             AuthenticationFailed
!             Timeout
!             NoSuccess
  Notes:      - This is a convenience routine built on the
!               create_job method, and is intended to simplify
!               the steps of creating a job_description,
!               creating and running the job, and then
!               querying the standard I/O streams.
!               - the I/O handles have to be passed to the call
!               as references, in most languages, as calls
!               often allow only one return value (perl or
!               python being notable exceptions). If these

```

```

!           parameters are omitted, the job is to be
              started non-interactively, and the output I/O
              streams may be discarded.
-           - the job is guaranteed to run on the given
              host, or not at all.
-           - the method is exactly equivalent to the
              sequence of (1) creation of a job_description
              with 'Executable'/Environment set to the
-           values from
+           with 'Executable' set to the values from the
              commandline, 'Interactive' set if I/O is
              requested, 'CandidateHost' set to host; (2)
              create_job() with that description; (3)
              calling run() on that job. This method can
              throw any of the exceptions which can occur in
              this sequence, with the semantics defined in
              the detailed description of the methods used
              in this sequence. No other exception are to
              be expected.
-           - if 'host' is an empty string (the default),
!           the implementation MUST choose an arbitrary
              host for execution.
+           - stdin, stdout and stderr are guaranteed to
+           contain/provide the complete standard I/O
+           streams, beginning at the start of the remote
+           process.

- list
  Purpose:  Get a list of jobs which are currently known by
            the resource manager.
  Format:   list                (out array<string>   job_ids);
  Inputs:   -
+  InOuts:  -
  Outputs:  job_ids:            an array of job identifiers
+  PreCond: -
+  PostCond: -
+  Perms:   Query on jobs identified by the returned ids
  Throws:   NotImplemented
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
+  Notes:   - which jobs are viewable by the calling user
+           context, and how long a resource manager keeps

```

```

+         job information, are both implementation
+         dependent.
-         a returned job_id may translate into a job
           (via get_job()) which is not controllable by
           the requesting application (e.g. it could
!         cause an 'AuthorizationFailed' exception).
-         The semantics of which jobs are viewable by
-         the calling user context, or how long a
-         resource manager keeps job information, are
-         implementation dependent.

- get_job
  Purpose: Given a job identifier, this method returns a
           job object representing this job.
  Format:  get_job          (in string job_id,
                           out job   job)
  Inputs:  job_id:         job identifier as returned
                           by the resource manager
+  InOuts: -
  Outputs: job:            a job object representing
                           the job identified by
                           job_id
+  PreCond: - job identified by job_id is managed by the
+             job_service.
+  PostCond: -
+  Perms:   Query on the job.
  Throws:  NotImplemented
           BadParameter
           DoesNotExist
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:   - in general, only a job_service representing the
           resource manager which submitted the job may be
           able to handle the job_id, and to identify the
           job -- however, other job_services may succeed
           as well.
           - if the resource manager can handle the job_id,
           but the referenced job is not alive, a
           'DoesNotExist' exception is thrown.
           - if the resource manager cannot parse the job_id
           at all, a 'BadParameter' exception is thrown.

```

```

- get_self
  Purpose: This method returns a job object representing
           _this_ job, i.e. the calling application.
  Format:  get_self          (out job_self self)
  Inputs:  -
+ InOuts:  -
  Outputs: self:              a job_self object
                             representing _this_ job.
+ PreCond: - the application is managed by the job_service.
+ PostCond: - job_self is, by definition, in 'Running'
+           state.
+ Perms:    Query on the job.
  Throws:   NotImplemented
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:    - in general, only a job_service representing the
             resource manager which started the application
             which now calls get_self() can successfully
             return a job_self instance. However, other
             job_services may succeed as well.
             - if a job_service cannot handle the calling job
             as a job_self instance, a 'NoSuccess' exception
!           is thrown, with a descriptive error message.

```

Class job

The `job` provides the manageability interface to a job instance submitted to a resource manager. There are two general types of methods: those for retrieving job state and information, and those for manipulating the job. The methods intended to manipulate jobs cannot make any guarantees about *how* the resource manager will **affect** an action to be taken. The API implementation is designed to be agnostic of the backend implementation, *such that any backend could be implemented to perform an action*. For example, the checkpoint routine might cause an application level checkpoint, or might use the services of GridCPR.

Job implements the `saga::attributes` interface. If not noted otherwise, none of these attributes is available before the job is running, and none is guaranteed to have a non-empty value while the job is running or after the job finishes.

Job also implements the monitorable interface, and thus allows monitoring and **notification** for changes of **runtime** attributes.

```

- - CONSTRUCTOR
-   Purpose:  create the object
-   Format:   CONSTRUCTOR      (out job obj);
-   Inputs:   -
-   InOuts:   -
-   Outputs:  obj:              the newly created object
-   PreCond:  -
-   PostCond: - job is in 'Unknown' state.
-   Perms:    -
-   Throws:   NotImplemented
-   Notes:    - the CONSTRUCTOR serves only the purpose to
-               create jobs to be passed by reference to
-               the asynchronous create_job method of the
-               job_service class.
-               - if any method other than the DESTRUCTOR is
-               called on the created job before it was
-               initialized by an asynchronous call to
-               create_job(), an 'IncorrectState' exception
-               MUST be thrown.
-
- - DESTRUCTOR
-   Purpose:  destroy the object
-   Format:   DESTRUCTOR      (in job obj)
-   Inputs:   obj:              the object to destroy
+   InOuts:   -
-   Outputs:  -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
!   Throws:   -
-   Notes:    - the object destruction does not imply a
-               call to cancel() for the job instance.

- get_job_description
-   Purpose:  Retrieve the job_description which was used to
-               submit this job instance.
-   Format:   get_job_description (out job_description jd);
-   Inputs:   -
+   InOuts:   -

```

```

      Outputs:  jd:                a job_description object
+      PreCond:  -
+      PostCond: - jd is deep copied (no state is shared
+                  after method invocation)
+      Perms:    Query
      Throws:    NotImplemented
                  DoesNotExist
-              IncorrectState
                  PermissionDenied
                  AuthorizationFailed
                  AuthenticationFailed
                  Timeout
                  NoSuccess
      Notes:     - There are cases when the job_description is not
                  available. This may include cases when
                  the job was not submitted through
                  SAGA and get_job() was used to retrieve the
                  job, or when this state information has been
                  lost (e.g. the client application restarts and
                  the particular SAGA implementation did not
                  persist the information). In that case, a
!              'DoesNotExist' exception is thrown, with a
                  descriptive error message.

- get_stdin
  Purpose:  retrieve input stream for a job.
  Format:   get_stdin            (out opaque stdin)
  Inputs:   -
+  InOuts:  -
  Outputs:  stdin:                standard input stream for
                                  the job
+  PreCond: - the job is interactive.
+  PostCond: - the jobs standard input stream is available
+             at stdin.
+  Perms:    Write (application can write to the jobs stdin).
  Throws:    NotImplemented
              BadParameter
              DoesNotExist
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
!  Notes:    - if the preconditions are met, but the standard

```

```

        input stream is not available for some
        reason, a 'DoesNotExist' exception is thrown.
+       - the stream MUST be valid until the job reaches
+       a final state. If it is, for some reason,
+       disconnected earlier, a language typical error
+       message is thrown (e.g. EBADF could be
+       returned on writes on that stream in C).
+       - if the job is not interactive, e.g. it was
+       submitted with the 'Interactive' attribute set
+       to 'False', an 'IncorrectState' exception is
+       thrown.
+       - if the job is not in 'New' state, it is not
+       guaranteed that the job did not receive other
+       data on its standard input stream before.

- get_stdout
  Purpose: retrieve output stream of job
  Format:  get_stdout          (out opaque stdout)
  Inputs:  -
+  InOuts: -
  Outputs: stdout:             standard output stream for
                               the job
+  PreCond: - the job is interactive.
+  PostCond: - the jobs standard output stream is available
+             from stdout.
+  Perms:   Read (application can read the jobs stdout).
  Throws:  NotImplemented
           BadParameter
           DoesNotExist
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
!  Notes:  - if the preconditions are met, but the standard
           output stream is not available for some
           reason, a 'DoesNotExist' exception is thrown.
+         - the stream MUST be valid until the job reaches
+         a final state. If it is, for some reason,
+         disconnected earlier, a language typical error
+         message is thrown (e.g. EBADF could be
+         returned on reads on that stream in C).
+         - if the job is not interactive, e.g. it was
+         submitted with the 'Interactive' attribute set

```

```

+           to 'False', an 'IncorrectState' exception is
+           thrown.
+       - if the job is not in 'New' state, it is not
+         guaranteed that the job did write data on
+         its standard output stream before, which are
+         then not returned on the returned stream.

- get_stderr
  Purpose: retrieve error stream of job
  Format:  get_stderr          (out opaque stderr)
  Inputs:  -
+  InOuts: -
  Outputs: stderr:            standard error stream for
                             the job
+  PreCond: - the job is interactive.
+  PostCond: - the jobs standard error stream is available
+             from stderr.
+  Perms:   Read (application can read the jobs stderr).
  Throws:  NotImplemented
           BadParameter
           DoesNotExist
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
!  Notes:  - if the preconditions are met, but the standard
           error stream is not available for some
           reason, a 'DoesNotExist' exception is thrown.
+         - the stream MUST be valid until the job reaches
+           a final state. If it is, for some reason,
+           disconnected earlier, a language typical error
+           message is thrown (e.g. EBADF could be
+           returned on reads on that stream in C).
+         - if the job is not interactive, e.g. it was
+           submitted with the 'Interactive' attribute set
+           to 'False', an 'IncorrectState' exception is
+           thrown.
+         - if the job is not in 'New' state, it is not
+           guaranteed that the job did write data on
+           its standard error stream before, which are
+           then not returned on the returned stream.

```

Job Management Methods:

- suspend
 - Purpose: Ask the resource manager to perform a suspend operation on the running job.
 - Format: suspend (void);
 - Inputs: -
 - + InOuts: -
 - + Outputs: -
 - + PreCond: - the job is in 'Running' state.
 - + PostCond: - the job is in 'Suspended' state.
 - + Perms: Exec (job can be controlled).
 - Throws: NotImplemented
IncorrectState
PermissionDenied
AuthorizationFailed
AuthenticationFailed
Timeout
NoSuccess
 - ! Notes: - if the job is not in 'Running' state, an 'IncorrectState' exception is thrown.

- resume
 - Purpose: Ask the resource manager to perform a resume operation on a suspended job.
 - Format: resume (void);
 - Inputs: -
 - + InOuts: -
 - + Outputs: -
 - + PreCond: - the job is in 'Suspended' state.
 - + PostCond: - the job is in 'Running' state.
 - + Perms: Exec (job can be controlled).
 - Throws: NotImplemented
IncorrectState
PermissionDenied
AuthorizationFailed
AuthenticationFailed
Timeout
NoSuccess
 - ! Notes: - if the job is not in 'Suspended' state, an 'IncorrectState' exception is thrown.

- checkpoint

```

        Purpose: Ask the resource manager to initiate a checkpoint
                  operation on a running job.
        Format:   checkpoint          (void);
        Inputs:   -
+       InOuts:  -
        Outputs:  -
+       PreCond: - the job is in 'Running' state.
+       PostCond: - the job is in 'Running' state.
+               - the job was checkpointed.
+       Perms:   Exec (job can be controlled).
        Throws:  NotImplemented
                  IncorrectState
                  PermissionDenied
                  AuthorizationFailed
                  AuthenticationFailed
                  Timeout
                  NoSuccess
!       Notes:   - The semantics of checkpoint(), and the actions
!                 taken to initiate a checkpoint, are resource
!                 manager specific. In particular, the
!                 implementation or backend can trigger either
!                 a system level or an application level
!                 - if the job is not in 'Running' state,
!                 an 'IncorrectState' exception is thrown.

- migrate
        Purpose: Ask the resource manager to migrate a job.
        Format:   migrate          (in job_description jd);
        Inputs:   jd:              new job parameters to apply
                                   when the job is migrated
+       InOuts:  -
        Outputs:  -
+       PreCond: - the job is in 'Running' or 'Suspended' state.
+       PostCond: - the job keeps its state.
+               - jd is deep copied (no state is shared
+                 after method invocation)
+               - the job reflects the attributes specified in
+                 the job_description.
+       Perms:   Exec (job can be controlled).
        Throws:  NotImplemented
                  BadParameter
                  IncorrectState
                  AuthorizationFailed
                  AuthenticationFailed
                  PermissionDenied

```

```

Timeout
NoSuccess
Notes:  - jd might indicate new resource
        requirements, for example.
        - the action of migration might change the job
        identifier within the resource manager.
        - ideally, the submitted job description was
        obtained by get_job_description(), and then
!       changed by the application. This is not a
-       condition though.
+       requirement though.
        - if the job is not in 'Running' or 'Suspended'
!       state, an 'IncorrectState' exception is thrown.
!       - the method can call the same exceptions as
        the submit_job() and run() methods, in
        particular in respect to an incorrect
        job_description.

- signal
  Purpose: Ask the resource manager to deliver an arbitrary
           signal to a dispatched job.
  Format:  signal          (in int signum);
  Inputs:  signum:         signal number to be
                           delivered
+  InOuts:  -
  Outputs:  -
+  PreCond: - job is in 'Running' or 'Suspended' state.
+  PostCond: - the signal was delivered to the job.
+  Perms:   Exec (job can be controlled).
  Throws:   NotImplemented
            BadParameter
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
Notes:     - there is no guarantee that the signal number
            specified is valid for the operating system
            on the execution host where the job is
            running, or that the signal can be delivered.
!          - if the signal number is not supported by the
            backend, a 'BadParameter' exception is thrown.
          - if the job is not in 'Running' or 'Suspended'
!          state, an 'IncorrectState' exception is

```

thrown.

Class `job_self`

The `job_self` class IS-A job which represents the current application (i.e. the very application which owns that `job_self` instance). It can only be created by calling `get_self()` on a job service (that call can fail though).

The motivation to introduce this class is twofold: (1) it allows to actively handle the current application as a grid job (e.g. to migrate it, or to obtain its job description for cloning/spawning); (2) as the class implements the steerable interface, it is possible to add `ReadWrite` metrics to its instance – that way it is possible to expose these metrics to other external applications, which in fact allows to steer the current application.

A drawback of this approach is that, in order to make an application steerable, a `job_service` instance is needed which can in fact return a `job_self` instance, which means there must be a resource manager available which can manage the current application – that however has nothing to do with the concept of remote steering. Future versions of the SAGA API may change that, and may make `job_self` a singleton, independent from the `job_service` behaviour. As a result, that class might disappear, and might not be maintained for backward compatibility.

```

-   - CONSTRUCTOR
-   Purpose:  create the object
-   Format:   CONSTRUCTOR          (out job_self self);
-   Inputs:   -
-   InOuts:   -
-   Outputs:  self:                  the newly created object
-   PreCond:  -
-   PostCond: - self is in 'Unknown' state
-   Perms:    -
-   Throws:   NotImplemented
-   Notes:    - the constructor serves only the purpose to
-               create jobs to be passed by reference to
-               the asynchronous get_self method of the
-               job_service class.
-               - if any method other than the DESTRUCTOR is
-               called on the created job_self before it was
-               initialized by an asynchronous call to
-               get_self(), an 'IncorrectState' exception

```

```

-           MUST be thrown.
-
-
-   - DESTRUCTOR
-     Purpose:  destroy the object
-     Format:   DESTRUCTOR          (in job_self obj)
-     Inputs:  obj:                  the object to destroy
+   InOuts:   -
-     Outputs: -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
-     Throws:  -
-     Notes:   - the object destruction does not imply a
-               call to cancel() for the job_self instance.

```

4.1.8 Examples

Code Example

```

1   Example : simple job submission and polling for finish.
2
3   // -----
4   // c++ example
5   std::list <std::string>   transfers;
6   saga::job_description jobdef;
7   saga::job_service      js;
8
9   transfers.push_back ("infile > infile");
10  transfers.push_back ("ftp://host.net/path/out << outfile");
11
12  jobdef.set_attribute      ("CandidateHost", "hostname");
13  jobdef.set_attribute      ("Executable",    "job.sh");
14  jobdef.set_attribute      ("TotalCPUCount", "16");
15  jobdef.set_vector_attribute ("FileTransfer", transfers);
16
17  saga::job job = js.create_job (jobdef);
18
19  job.run ();
20
21  while ( 1 )
22  {
23      // get job state
24      saga::job::state state = job.get_state ();
25
26      // get list of hosts the job is/where running on
27      std::list <std::string> hostlist = job.get_attribute

```

```
28                                     ("ExecutionHosts");
29
30     if ( saga::job::Running == state )
31     {
32         std::cout << "Job is running." << std::endl;
33     }
34     else if ( saga::job::Suspended == state )
35     {
36         std::cout << "Job is suspended." << std::endl;
37     }
38     else if ( saga::job::Done == state )
39     {
40         std::cout << "Job completed successfully." << std::endl;
41         exit (0);
42     }
43     else if ( saga::job::Canceled == state )
44     {
45         // this should never occur, as cancel is not called.
46         std::cout << "Job canceled." << std::endl;
47         exit (1);
48     }
49     else
50     {
51         // state can only be 'Failed'
52         assert (saga::job::Failed == state);
53
54         std::string exitcode = job.get_attribute ("ExitCode");
55
56         std::cout << "Job failed with exitcode:"
57                 << exitcode
58                 << std::endl;
59         exit ( atoi(exitcode) );
60     }
61
62     sleep (1); // idle
63 }
```

4.2 SAGA Name Spaces

Several SAGA packages share the notion of name spaces and operations on these name spaces. In order to increase consistency in the API, **these** packages share the same API paradigms. This section describes those paradigms, and **these** classes which operate on arbitrary hierarchical **name spaces**, such as used in physical, virtual, and logical file systems, and in information systems.

The API is inspired by the POSIX standard, which defines tools and calls to handle the name space of physical files *and* directories. The methods listed for the interfaces have POSIX-like syntax and semantics.

While POSIX has an iterative interface to directory listing (i.e. `opendir`, `telldir`, `seekdir`, `readdir`), the corresponding part of the interface included here deviates significantly from the POSIX version: it has fewer calls, with a different syntax, but identical semantics.

Please note that 'stat'-like API calls are *not* covered here – they are rather meaningless on a name space per se, but belong to the specific implementations, e.g. physical files, which *inherit* the **namespace classes**.

4.2.1 Definitions

The Grid File System Working Group in OGF has defined a Resource Name-space Service (RNS [20]). The SAGA Core API specification follows the definition of a name space from that document.

Directory: A 'Directory' represents what [20] defines as 'Virtual Directory':

“A virtual directory is an RNS entry that is represented as a non-leaf node in the hierarchical name space tree. When rendered by a name space service client, a virtual directory functions similar to that of a standard filesystem directory or registry key. It is considered virtual because it does not have any corresponding representation outside of the name space. A virtual directory, therefore, is purely a name space entity that functions in much the same way as a conventional filesystem directory or registry key by maintaining a list of subentries, which thereby demonstrate a hierarchical relationship. There are no restrictions regarding the layout of the name space tree; both virtual directories and junctions can be nested within nested virtual directories recursively.

A virtual directory may be considered analogous to a collection, category, or context – to the extent that these terms are used in most directory, registry, or catalogue contexts. Virtual directories do not have any time or space existence outside of the name space and strictly serve to facilitate hierarchy. Name space hierarchies offer categorization or grouping

of entries, by presenting the illusion of compartments, which may contain sub-compartments as well as junctions.”

Directory Entry: A *directory entry* or *entry* represent what [20] defines as ‘Junction’. Note that any type of junction defined there could be used:

“A junction is an RNS entry that interconnects a reference to an existing resource into the hierarchical name space. Junctions represent a name-to-resource mapping that is composed of a human oriented index key or ‘name’ that maps to an endpoint reference. The endpoint reference may refer to any addressable resource, which includes other name space entries, as well as names or unique identifiers to be resolved by other resolution service, as well as definitive target consumable resource. All compliant RNS implementations MUST embody the target information of a name space junction within a valid WS-Addressing [...] Endpoint Reference (EPR).”

Pathnames: A *pathname* as accepted by this specification MUST be either formatted as URLs or MUST follow the specification of entry names as described *in section 1.2.2.1 “Entry Name Restrictions” in [20] in [20], Section 1.2.2.1 “Entry Name Restrictions”* (formatting changed):

“Entry names are composed of a simple string of human readable characters. Since certain characters serve special purposes both within the name space service and within a number of systems that may use this service, this section describes the mandatory restrictions for all entry names:

Names MUST NOT...

- *Contain any of the following characters: / : ; * ? " < > |*
- *Contain any non-readable characters, such as the carriage return (ANSI 13) or line feed (ANSI 10) or tab (ANSI 9)*
- *Be greater than 255 characters in length (Unicode)*

Names SHOULD...

- *Accommodate Unicode characters*
- *Be easily readable by a human user, suggesting less than 32 characters per name*

Names MAY...

- *Contain space (ANSI 32) characters*

Notice these restrictions apply to entry names and are not describing paths. Paths are constructed of one or more entry names separated by the forward slash character (/).

Note that, in fact, pathnames as specified above are syntactically valid URLs, and this specification is therefore only referring to URLs. Both, SAGA implementations and SAGA usage SHOULD, however, strive for compliance with [20]. An exception is the use of relative pathnames which, in SAGA, can contain wildcards (see below).

If pathnames are specified as URLs, the path section of the URL MUST follow the guidelines for pathnames as cited above, and MUST NOT contain any parameter, query or fragment parts.

*Additionally, **pathname** specifications in SAGA can contain wildcards as specified below.*

All method arguments which are named **name**, **source** or **target** are considered pathnames. These pathnames can always be relative pathnames (i.e. they can be relative to the *current working directory* (**cwd**) of the object instance the operation is performed upon, e.g. when they start with `'./'` or `'../'`).

Note that the comments from Section 2.11, apply here. In particular, an implementation MAY throw an **IncorrectURL** exception if it is unable to handle a given *URL*, e.g. *because of its scheme*.

Current Working Directory (cwd) Every `saga::ns_entry` instance has an associated current working directory (**cwd**), which forms the implicit base for all operations on relative pathnames. For `saga::ns_directory` instances, that **cwd** can be changed with the `change_dir` method. Otherwise, **cwd** only changes if the entry itself is `move()`'d.

Links: *Links* in this specification are considered *symbolic links*, i.e. they can break if the entry they point to is removed. An implementation MAY support links, as not all backends can support links, and others might support links only in specific circumstances (e.g. if entry and link live on the same file system).

The 'Dereference' flag allows methods to operate on the link target instead of the link – only one level of reference is resolved though. The `read_link()` method does also resolve only one link level, and returns **a** URL pointing to the link target.

At the **moment**, [20] does not have a notion of symbolic links. However, an RNS 'junction' which is associated with another RNS junction can be regarded as **a** symbolic link.

Wildcards: The API supports wildcards *where appropriate for a number of calls, as listed below*, and thereby follows the POSIX standard [21, 22, 23] for shell wildcards. Available wildcard patterns are:

```

*           : matches any string
?           : matches a single character
[abc]       : matches any of a set of characters
[a-z]       : matches any of a range of characters
[!abc]      : matches none of a range of characters
[!a-z]      : matches none of a range of characters
{a,bc}      : matches any of a set of strings

```

See the POSIX standard [21, 22, 23] for more details. In the *SAGA* API, wildcards are allowed in all pathnames where they can be used in the respective shell commands, as:

```

copy    *.txt dir
move    *.txt dir
link    *.txt dir
ls      *.txt
remove  *.txt

```

Users are rarely aware that wildcards can be used in unorthodox places, such as:

```

move *.txt dir*
move *

```

The result of such operations is dependent on the order the wildcard expansion is performed, e.g. if 'dir' expands to 'dir.1 dir.2', all txt files and dir.1 will end up in dir.2. SAGA implementations MUST support wildcards for all pathnames where that ambiguity cannot arise. (source for move etc.), and MAY support wildcards at all pathnames where that ambiguity may arise.*

For the method calls on `saga::ns.entry`, no wildcards are allowed. Note that the methods `read.link()`, `exists()`, `is.dir()`, `is.entry()`, `is.link()`, `open()`, and `open.dir()` MUST NOT support wild cards (their return values make only sense in respect to a single entry). Note that only those methods MUST support wildcards for which this is explicitly specified here. Other methods MUST NOT support wildcards, as this would not be meaningful. Flags MUST be applied to all elements of a wildcard expansion, even if that raises an exception for any reason.

For the use of wildcards, separate calls are provided which accept strings instead of URLs. The reason for this is that RFC 3986 [5], which defines the syntax of URLs, explicitly forbids most POSIX wildcard characters as part of a URL. Also, we feel that wildcards make most sense in relative pathnames (i.e. relative to a working directory). Strings in these separate calls thus MUST be relative paths,

and thus MUST only contain URL path elements, whereby the path element MUST NOT start with an '/'. Apart from that, the semantics of the wildcard-enabled string method versions of the calls are identical to the semantics of their respective URL counterparts. If the method encounters any error condition on any one of the expanded URLs, an exception is thrown, and the state of the other (valid or invalid) expanded URL targets remains undefined.

a long section about ACLs got removed

Opening and Closing Name Space Entries: If a `ns_entry` object instance gets created, it is also opened. Hence, the semantics and all notes of the **respective** `open()` call also apply to the constructor. The same holds for all classes that inherit `ns_entry`.

In accordance with Section 2.5.4, the `saga::ns_entry` class has a `close()` method, which allows to enforce a timely release of used (local and remote) resources. After a `ns_entry` instance was closed, all **method** calls on that instance (apart from the **DESTRUCTOR**) MUST throw an **IncorrectState** exception. A destruction of an entry implies the respective `close()` semantics. The same holds for all classes that inherit `ns_entry`.

If an entry gets successfully opened without specifying 'Lock' as open flag, its state may get corrupted if some other backend operation removes or moves the opened entity, or changes its state. In that case, any subsequent operation on the object instance can fail unexpectedly. An **IncorrectState** exception describing the type of state change SHOULD be thrown if such a state change is detected and causes an operation to fail. Otherwise, the normal exception indicating the type of error which occurred **SHOULD** be thrown. The **IncorrectState exception** is thus listed on most method calls below, but not individually motivated unless it is also used in any other semantic context.

```

4.2.3 Specification Details

Enum flags

*The **flags** describe the properties of several operations on namespace entries. Packages which inherit from the namespace package use the same flag semantics unless specified otherwise, but will, in general, add additional flags to some operations.*

None

indicates the absence of flags, and thus also implies that the default flags for an operation do not apply, either.

Overwrite

*enforces an operation which creates a new namespace entry to continue even if the target entry does already exist – if that flag is not given, an **'AlreadyExists'** exception would result from such an operation.*

Recursive

enforces an operation to apply recursively on a directory tree – if that flag is not given, the same operation would only apply to the given directory, and not to its children.

Dereference

enforces an operation to apply not to the entry pointed to by the target name, but to the link target of that entry – if that flag is not given, the same operation would apply to the entry directly, and its link target stays unaffected.

Create

*allows a namespace entry to be created while opening it, if it does not already exist – if that flag is not given, the same open operation would cause a **'DoesNotExist'** exception. If the entry exists, the flag is ignored.*

Exclusive

*implies a modification to the meaning of the **Create** flag: if the entry already exists, the **Create** flag is no longer silently ignored, but causes an **'AlreadyExists'** exception.*

Lock

*enforces a lock on the name space entry when it is opened. Locks are advisory in SAGA, semantic details for locking are defined in the description of the **open()** call.*

CreateParents

An operation which would create a name space entry would normally fail if any path element in the targets name does not yet exist. If this flag is given, such an operation would not fail, but would imply that the missing path elements are created on the fly.

Class ns_entry

`ns_entry` defines methods which serve the inspection of the entry itself, methods which allows to manage the entry (e.g. to copy, move, or remove it), and methods to manipulate the **entry's** access control lists.

In general, multiple such URLs might be valid to identify an entry:

```
ftp://ftp.host.net/pub/data/test.txt
http://www.host.net/ftp/data/test.txt
http://www.host.net/ftp/data/./test.txt
http://www.host.net/ftp/data/../data/test.txt
```

Any valid URL can be returned on `get_url()`, but it SHOULD not contain `'..'` or `'.'` path elements, *i.e. should have a normalized path element*. The URL returned on `get_url()` should serve as base for the return values on `get_cwd()` and `get_name()`: *In general it should hold:*

```
get_url() = get_cwd() + '/' + get_name()
```

- Constructor / Destructor:

-

- CONSTRUCTOR

Purpose: create the object

```
!   Format:  CONSTRUCTOR          (in session s,
                                   in saga::url name,
                                   in int      flags = None,
                                   out ns_entry obj)

!   Inputs:  s:                   session handle
              name:                initial working dir
              flags:               open mode

+   InOuts:  -
              Outputs: obj:        the newly created object
+   PreCond: -
+   PostCond: - the entry is opened.
+              - 'Owner' of target is the id of the context
```

```

+           use to perform the operation, if the
+           entry gets created.
+   Perms:   Exec   for parent directory.
+           Write for parent directory if Create is set.
+           Write for name if Write is set.
+           Read  for name if Read  is set.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           DoesNotExist
+           AlreadyExists
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
!   Notes:  - the default flags are 'None' (0)
+           - the constructor performs an open of the
+             entry - all notes to the respective open
+             call (on namespace_directory) apply.

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR           (in ns_entry   obj)
  Inputs:   obj:                 the object to destroy
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - the entry is closed.
+   Perms:   -
+   Throws:  -
  Notes:    - if the instance was not closed before, the
!           destructor performs a close() on the instance,
+           and all notes to close() apply.

```

Methods for inspecting ns_entry:

```

- get_url
  Purpose:  obtain the complete url pointing to the entry
  Format:   get_url             (out saga::url url);
  Inputs:   -
+   InOuts:  -

```

```

        Outputs:  url                url pointing to the entry
+       PreCond:  -
+       PostCond: -
+       Perms:    -
        Throws:   NotImplemented
                IncorrectState
                Timeout
                NoSuccess
+       Notes:    -
-       Notes:    - if the instance was not opened before, an
-                   'IncorrectState' exception is thrown.

- get_cwd
  Purpose:  obtain the current working directory for the
            entry
  Format:   get_cwd                (out saga::url cwd);
  Inputs:   -
+  InOuts:  -
  Outputs:  cwd                    current working directory
+  PreCond:  -
+  PostCond: -
+  Perms:    -
  Throws:   NotImplemented
            IncorrectState
            Timeout
            NoSuccess
+  Notes:    -
-  Notes:    - if the instance was not opened before, an
-               'IncorrectState' exception is thrown.
+               - returns the directory part of the url path
+               element.

- get_name
  Purpose:  obtain the name part of the url path element
  Format:   get_name                (out saga::url name);
  Inputs:   -
+  InOuts:  -
  Outputs:  name                    last part of path element
+  PreCond:  -
+  PostCond: -
+  Perms:    -
  Throws:   NotImplemented

```

```

IncorrectState
Timeout
NoSuccess
+   Notes: -
-   Notes: - if the instance was not opened before, an
-           'IncorrectState' exception is thrown.

- is_dir
!   Purpose: tests the entry for being a directory
-   Format:  is_dir          (in int    flags = None,
+   Format:  is_dir          (out boolean test);
!   Inputs:  -
+   InOuts:  -
Outputs: test:          boolean indicating if entry
                        is a directory
+   PreCond: -
+   PostCond: -
+   Perms:   Query
+           Query for parent directory.
Throws: NotImplemented
-         BadParameter
        IncorrectState
        PermissionDenied
        AuthorizationFailed
        AuthenticationFailed
        Timeout
        NoSuccess
Notes: - returns true if entry is a directory, false
        otherwise
-       - flags can be set to 'Dereference', the default
-       - is 'None' (0).
-       - other flags are not allowed on this method,
-       - and cause a 'BadParameter' exception.
-       - if the instance was not opened before, an
-       - 'IncorrectState' exception is thrown.
-       - similar to 'test -d' as defined by POSIX.

- is_entry
!   Purpose: tests the entry for being an ns_entry
-   Format:  is_entry        (in int    flags = None,
+   Format:  is_entry        (out boolean test);
!   Inputs:  -
+   InOuts:  -

```

```

        Outputs: test:          boolean indicating if entry
!                               is an ns_entry
+   PreCond:  -
+   PostCond: -
+   Perms:    Query
+             Query for parent directory.
        Throws: NotImplemented
-             BadParameter
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
        Notes: - the method returns false if the entry is a
!              link or a directory (although an ns_directory
              IS_A ns_entry, false is returned on a test on
!              an ns_directory) - otherwise true is returned.
-              - flags can be set to 'Dereference', the default
-              is 'None' (0)
-              - other flags are not allowed on this method,
-              and cause a 'BadParameter' exception.
-              - if the instance was not opened before, an
-              'IncorrectState' exception is thrown.
!              - similar to 'test -f' as defined by POSIX.

- is_link
!   Purpose: tests the entry for being a link
-   Format:  is_link          (in int    flags = None,
+   Format:  is_link          (out boolean test);
!   Inputs:  -
+   InOuts:  -
        Outputs: test:          boolean indicating if
                               entry is a link
+   PreCond:  -
+   PostCond: -
+   Perms:    Query
+             Query for parent directory.
        Throws: NotImplemented
-             BadParameter
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout

```

```

                                NoSuccess
Notes:  - returns true if the entry is a link, false
        - otherwise
-       - flags can be set to 'Dereference', the default
-       - is 'None' (0)
-       - other flags are not allowed on this method,
-       - and cause a 'BadParameter' exception.
-       - if the instance was not opened before, an
-       - 'IncorrectState' exception is thrown.
!       - similar to 'test -L' as defined by POSIX.

- read_link
  Purpose: returns the name of the link target
  Format:  read_link          (out saga::url link);
  Inputs:  -
+  InOuts: -
  Outputs: link:              resolved name
+  PreCond: -
+  PostCond: -
+  Perms:   Query
+           Query for parent directory.
  Throws:  NotImplemented
-          BadParameter
-          IncorrectState
-          PermissionDenied
-          AuthorizationFailed
-          AuthenticationFailed
-          Timeout
-          NoSuccess
Notes:  - the returned name MUST be sufficient to
        - access the link target entry
        - resolves one link level only
        - if the entry instance this method is called
!       - upon does not point to a link, an
!       - 'IncorrectState' exception is thrown.
-       - if the instance was not opened before, an
-       - 'IncorrectState' exception is thrown.
-       - similar to 'ls -L' as defined by POSIX.

-
-
-  Methods for managing access control lists:
-  -----
-
-  - set_acl

```

```

- Purpose: set access control list for this entry
- Format:  set_acl          (in string dn,
-                               in int   acl,
-                               in int   flags = None);
- Inputs:  dn:              DN to set ACLs for
-          acl:              OR'ed ACLs to be set on the
-                               entity, for the specified dn
-          flags:            flags defining the operation
-                               modus
- Outputs: -
- Perms:   -
- Throws:  NotImplemented
-          BadParameter
-          IncorrectState
-          PermissionDenied
-          AuthorizationFailed
-          AuthenticationFailed
-          Timeout
-          NoSuccess
- Notes:   - if the entry is a directory and the 'Recursive'
-             flag is set, the ACLs are applied to all
-             entries in the directory tree below. If the
-             flag is set and the entry is not a directory, a
-             'BadParameter' exception is thrown.
-           - if the entry is a link and the 'Dereference'
-             flag is set, the ACLs are set for the link
-             target, and not for the link itself. If the
-             flag is set and the entry is not a link, a
-             'BadParameter' exception is thrown.
-           - other flags are not allowed, and cause a
-             'BadParameter' exception.
-           - the default flags are 'None' (0).
-           - invalid or inconsistent acl specifications
-             cause a 'BadParameter' exception with a
-             descriptive error message
-           - if the 'dn' cannot be parsed or evaluated, or
-             if some wildcard in the 'dn' is not supported,
-             a 'BadParameter' exception with a descriptive
-             error message is thrown.
-           - if the instance was not opened before, an
-             'IncorrectState' exception is thrown.
-
-
- - get_acl
- Purpose: get access control list for this entry
- Format:  get_acl          (in string dn,

```

226

```

-           PermissionDenied
-           AuthorizationFailed
-           AuthenticationFailed
-           Timeout
-           NoSuccess
-   Notes:  - if the entry is a link and the 'Dereference'
-            flag is set, the DNs are retrieved for the
-            link target, and not for the link itself.
-            If the flag is set and the entry is not a
-            link, a 'BadParameter' exception is thrown.
-            - other flags are not allowed, and cause a
-              'BadParameter' exception.
-            - the default flags are 'None' (0).
-            - the list of returned DNs can contain wildcards
-              as described earlier. These can be expanded
-              by the application if that is required, or can
-              be reused as they are.
-            - if the instance was not opened before, an
-              'IncorrectState' exception is thrown.
-

```

Methods for managing the name space entry:

```

-----

- copy
  Purpose: copy the entry to another part of the name space
  Format:  copy                               (in saga::url target,
                                              in int      flags = None);
  Inputs:  target:                           name to copy to
          flags:                             flags defining the operation
                                              modus
+   InOuts: -
+   Outputs: -
+   PreCond: -
+   PostCond: - an identical copy exists at target.
+               - 'Owner' of target is the id of the context
+                 use to perform the operation, if target gets
+                 created.
+   Perms:   Query
+             Exec for parent directory.
+             Query for target.
+             Query for target's parent directory.
+             Exec for target's parent directory.
+             Write for target
+               if target does exist.
+             Write for target's parent directory

```

```

+           if target does not exist.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           DoesNotExist
+           AlreadyExists
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes:   - if the target is a directory, the source entry
!             is copied into that directory
!           - a 'BadParameter' exception is thrown if the
!             source is a directory and the 'Recursive' flag
!             is not set.
!           - a 'BadParameter' exception is thrown if the
!             source is not a directory and the 'Recursive'
!             flag is set.
!           - if the target lies in a non-existing part of
!             the name space, a 'DoesNotExist' exception is
!             thrown, unless the 'CreateParents' flag is
!             given - then that part of the name space must
!             be created.
!           - if the target already exists, it will be
!             overwritten if the 'Overwrite' flag is set,
!             otherwise it is an 'AlreadyExists' exception.
+           - if a directory is to be copied recursively,
+             but the target exists and is not a directory,
+             and not a link to a directory, an
+             'AlreadyExists' exception is thrown even if
+             the 'Overwrite' flag is set.
!           - if the instance points at an symbolic link,
!             the source is deeply dereferenced before copy.
!             If dereferencing is impossible (e.g. on a broken
!             link), an 'IncorrectState' exception is thrown.
!           - other flags are not allowed, and cause a
!             'BadParameter' exception.
!           - the default flags are 'None' (0).
!           - similar to 'cp' as defined by POSIX.

- link
!   Purpose: create a symbolic link from the target entry to
!             the source entry ( this entry) so that any reference

```

```

!           to the target refers to the source entry
Format:    link           (in  saga::url target,
                          in  int      flags = None);
Inputs:    target:        name to link to
          flags:          flags defining the operation
                          modus
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - a symbolic link to the entry exists at target.
+               - 'Owner' of target is the id of the context
+               use to perform the operation if target gets
+               created.
+   Perms:   Query
+           Exec  for parent directory.
+           Query for target.
+           Query for target's parent directory.
+           Exec  for target's parent directory.
+           Write for target
+               if target does exist.
+           Write for target's parent directory
+               if target does not exist.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           DoesNotExist
+           AlreadyExists
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
Notes:      - if the target is a directory, the source entry
              is linked into that directory
              - if the source is a directory, and the
                'Recursive' flag is set, the source directory
                is recursively linked to the target (which must
                be a directory as well - otherwise a
                'BadParameter' exception is thrown). The
                method then behaves similar to lndir. If the
                'Recursive' flag is not set, the source entry
                itself is linked.
!           - a 'BadParameter' exception is thrown if the
              source is not a directory and the 'Recursive'
              flag is set.

```

```

- if the target lies in a non-existing part of
!   the name space, a 'DoesNotExist' exception is
    thrown, unless the 'CreateParents' flag is
    given - then that part of the name space must
    be created.
- if the target already exists, it will be
!   overwritten if the 'Overwrite' flag is set,
    otherwise it is an 'AlreadyExists' exception.
+   - if a directory is to be moved, but the target
+     exists and is not a directory, and not a link
+     to a directory, an 'AlreadyExists' exception
+     is thrown even if the 'Overwrite' flag is set.
- if the instance points at an symbolic link,
    the source is not dereferenced before linking,
    unless the 'Dereference' flag is given. If
    dereferencing is impossible (e.g. on a broken
    link), an 'IncorrectState' exception is thrown.
- other flags are not allowed, and cause a
!   'BadParameter' exception.
!   - the default flags are 'None' (0).
    - similar to 'ln' as defined by POSIX.

- move
  Purpose: rename source to target, or move source to
!         target if target is a directory.
  Format:  move                (in saga::url target,
                               in int      flags = None);
  Inputs:  target:             name to move to
          flags:               flags defining the operation
                               modus
+  InOuts: -
+  Outputs: -
+  PreCond: -
+  PostCond: - an identical copy exists at target.
+              - the original entry is removed.
+              - 'Owner' of target is the id of the context
+                use to perform the operation if target gets
+                created.
+  Perms:  Query
+          Write
+          Exec for parent directory.
+          Write for parent directory.
+          Query for target.
+          Exec for target's parent directory.
+          Write for target

```

```

+           if target does exist.
+       Write for target's parent directory
+           if target does not exist.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           DoesNotExist
+           AlreadyExists
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes:
+       - if the target is a directory, the source entry
+         is moved into that directory
+       - a 'BadParameter' exception is thrown if the
+         source is a directory and the 'Recursive' flag
+         is not set.
+       - a 'BadParameter' exception is thrown if the
+         source is not a directory and the 'Recursive'
+         flag is set.
+       - if the target lies in a non-existing part of
+         the name space, a 'DoesNotExist' exception is
+         thrown, unless the 'CreateParents' flag is
+         given - then that part of the name space must
+         be created.
+       - if the target already exists, it will be
+         overwritten if the 'Overwrite' flag is set,
+         otherwise it is an 'AlreadyExists' exception.
+       - if the instance points at an symbolic link,
+         the source is not dereferenced before moving,
+         unless the 'Dereference' flag is given.
+         If derefencing is impossible (e.g. on a broken
+         link), an 'IncorrectState' exception is thrown.
+       - other flags are not allowed, and cause a
+         'BadParameter' exception.
+       - the default flags are 'None' (0).
+       - similar to 'mv' as defined by POSIX.

- remove
  Purpose: removes this entry, and closes it
  Format:  remove          (in int flags = None);
  Inputs:  target:        entry to be removed
+   InOuts:  -

```

```

        Outputs: -
+       PreCond: -
+       PostCond: - the original entry is closed and removed.
+       Perms:   Query
+               Write
+               Exec  for parent directory.
+               Write for parent directory.
+       Throws:  NotImplemented
+               BadParameter
+               IncorrectState
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
!       Notes:   - a 'BadParameter' exception is thrown if the
+               source is a directory and the 'Recursive' flag
+               is not set.
!               - a 'BadParameter' exception is thrown if the
+               source is not a directory and the 'Recursive'
+               flag is set.
+               - the source will not be dereferenced unless the
+               'Dereference' flag is given. If dereferencing is
+               impossible (e.g. on a broken link), an
+               'IncorrectState' exception is thrown.
+               - other flags are not allowed, and cause a
!               'BadParameter' exception.
!               - the default flags are 'None' (0).
!               - if the instance was not closed before, this
!               call performs a close() on the instance, and
+               all notes to close() apply.
+               - similar to 'rm' as defined by POSIX.

- close
  Purpose: closes the object
  Format:  close          (in float timeout = 0.0);
  Inputs:  timeout        seconds to wait
+  InOuts: -
  Outputs: -
+  PreCond: -
+  PostCond: - the entry instance is closed.
+  Perms:   -
  Throws:  NotImplemented
+         IncorrectState
+         NoSuccess

```

```

- Notes: - 'IncorrectState' is thrown if the object was
-         closed or removed before.
Notes: - any subsequent method call on the object
!       MUST raise an 'IncorrectState' exception
!       (apart from DESTRUCTOR and close()).
- close() can be called multiple times, with no
  side effects.
+ - if close() is implicitly called in the
+   DESTRUCTOR, it will never throw an exception.
- - it is assumed that a session which opened the
-   instance can also close it - otherwise the
-   backend entity must have changed its state,
-   which causes an 'IncorrectState' exception.
- - for resource deallocation semantics, see
!   Section 2.
!   - for timeout semantics, see Section 2.
+
+
+ // overload permissions because of namespace specific flags
+
+ - permissions_allow
+   Purpose: enable a permission
+   Format:  permissions_allow    (in string id,
+                                   in int    perm,
+                                   in int    flags = None);
+   Inputs:  id:                  id to set permission for
+               perm:              permission to enable
+               flags:             mode of operation
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - the permissions are enabled.
+   Perms:   Owner
+   Throws:  NotImplemented
+           BadParameter
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes:   - all notes to permissions_allow from the
+             saga::permissions interface apply.
+             - allowed flags are: 'Recursive', 'Dereference'.
+             All other flags cause a 'BadParameter'
+             exception.

```

```

+           - specifying 'Recursive' for a non-directory
+             causes a 'BadParameter' exception.
+
+
+
+ - permissions_deny
+   Purpose:  disable a permission flag
+   Format:   permissions_deny      (in string      id,
+                                   in int          perm,
+                                   in int          flags);
+   Inputs:   id:                   id to set permission for
+               perm:                permission to disable
+               flags:               mode of operation
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: - the permissions are disabled.
+   Perms:    Owner
+   Throws:   NotImplemented
+             BadParameter
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
+   Notes:    - all notes to permissions_deny from the
+               saga::permissions interface apply.
+               - allowed flags are: 'Recursive', 'Dereference'.
+               All other flags cause a 'BadParameter'
+               exception.
+               - specifying 'Recursive' for a non-directory
+               causes a 'BadParameter' exception.

```

Class ns_directory

`ns_directory` inherits all navigation and manipulation methods from `ns_entry`, but adds some more methods to these sets: instead of `dir.copy (target)` they allow, for example, to do `dir.copy (source, target)`. Other methods added allow to change the cwd of the instance (which changes the values returned by the `get_name()`, `get_cwd()` and `get_url()` inspection methods), and others allow to open new `ns_entry` and `ns_directory` instances (`open()` and `open_dir()`).

For all methods which have the same name as in the `ns_entry` class, the descriptions and semantics defined in `ns_entry` apply, unless noted here otherwise.

```

- Constructor / Destructor:
- -----
-
- CONSTRUCTOR
  Purpose: create the object
!   Format:  CONSTRUCTOR      (in session s,
                                in saga::url name,
                                in int flags = None,
                                out ns_directory obj)
                                initial working dir
                                open mode
!   Inputs:  name:             session handle for
                                object creation
                                flags:
!   s:
+   InOuts:  -
+   Outputs: obj:             the newly created object
+   PreCond: -
+   PostCond: - the directory is opened.
+               - 'Owner' of target is the id of the context
+                 use to perform the operation, if the
+                 directory gets created.
+   Perms:   Exec for parent directory.
+             Write for parent directory if Create is set.
+             Write for name if Write is set.
+             Read for name if Read is set.
+   Throws:  NotImplemented
+             IncorrectURL
+             BadParameter
+             DoesNotExist
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
+   Notes:   - the semantics of the inherited constructors
+             apply
+             - the constructor performs an open of the
+               entry - all notes to the respective open
+               call apply.
!   - the default flags are 'None' (0).

```

```

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR          (in ns_directory obj)
  Inputs:   obj:                the object to destroy
+  InOuts:   -
  Outputs:   -
+  PreCond:   -
+  PostCond:  - the directory is closed.
+  Perms:     -
  Throws:    -
  Notes:     - the semantics of the inherited destructors
               apply

```

Methods for navigation in the name space hierarchy:

```

- change_dir
  Purpose:  change the working directory
  Format:   change_dir          (in saga::url dir);
  Inputs:   dir:                directory to change to
+  InOuts:   -
  Outputs:   -
+  PreCond:   -
+  PostCond:  - dir is the directory the instance represents.
+  Perms:     Exec for dir.
  Throws:    NotImplemented
              IncorrectURL
              BadParameter
              DoesNotExist
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
!  Notes:    - if 'dir' can be parsed as URL, but contains an
!             invalid directory name, a 'BadParameter'
              exception is thrown.
              - if 'dir' does not exist, a 'DoesNotExist'
              exception is thrown.
!             - similar to the 'cd' command in the POSIX
!             shell.

- list

```

```

    Purpose: list entries in this directory
!   Format:  list          (in  string name_pattern = ".",
                           in  int   flags      = None
                           out array<saga::url> names);
    Inputs:  flags:        flags defining the operation
                           modus
                           name_pattern:      name or pattern to list
+   InOuts:  -
    Outputs: names:        array of names matching the
                           name_pattern
+   PreCond: -
+   PostCond: -
+   Perms:   Query for entries specified by name_pattern.
+           Exec for parent directories of these entries.
+           Query for parent directories of these entries.
+           Read for directories specified by name_pattern.
+           Exec for directories specified by name_pattern.
+           Exec for parent directories of these directories.
+           Query for parent directories of these directories.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
!   Notes:   - if name_pattern is not given (i.e. is an empty
+           string), all entries in the current working
+           directory are listed.
+           - if name_pattern is given and points to a
+           directory, the contents of that directory
+           are listed.
+           - the name_pattern follows the standard POSIX
+           shell wildcard specification, as described
+           above.
+           - list does not follow symbolically linked
+           directories, unless the 'Dereference' flag
+           is specified - otherwise list lists symbolic
!           link entries with a matching name.
+           - if the 'DeReference' flag is set, list
+           returns the name of link targets, not of the
+           link entry itself.
!           - the default flags are 'None' (0).
+           - other flags are not allowed, and cause a

```

```

        'BadParameter' exception.
    - if the name_pattern cannot be parsed, a
!   'BadParameter' exception with a descriptive
      error message is thrown.
    - if the name_pattern does not match any entry,
      an empty list is returned, but no exception is
      raised.
    - similar to 'ls' as defined by POSIX.

- find
  Purpose: find entries in the current directory and below
  Format:  find          (in string name_pattern,
                        in int   flags = Recursive,
                        out array<saga:url> names);

  Inputs:  name_pattern: pattern for names of
                        entries to be found
           flags:         flags defining the operation
                        modus

+   InOuts: -
  Outputs: names:         array of names matching the
                        name_pattern

+   PreCond: -
+   PostCond: -
+   Perms:   Read  for cwd.
           Query for entries specified by name_pattern.
           Exec  for parent directories of these entries.
           Query for parent directories of these entries.
           Read  for directories specified by name_pattern.
           Exec  for directories specified by name_pattern.
           Exec  for parent directories of these directories.
           Query for parent directories of these directories.

  Throws:   NotImplemented
           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess

!   Notes:  - find operates recursively below the current
            working directory if the 'Recursive' flag is
            specified (default)
            - find does not follow symbolically linked
              directories, unless the 'Dereference' flag
              is specified - otherwise find lists symbolic

```

```

!           link entries with a matching name.
-           - if the 'DeReference' flag is set, list
-             returns the name of link targets, not of the
-             link entry itself.
!           - the default flags are 'Recursive' (1).
-           - other flags are not allowed, and cause a
-             'BadParameter' exception.
!           - the name_pattern follows the standard POSIX
-             shell wildcard specification, as described
-             above.
!           - the matching entries returned are path names
!           relative to cwd.
-           - similar to 'find' as defined by POSIX, but
-             limited to the -name option.

- exists
  Purpose:  returns true if entry exists, false otherwise
  Format:   exists                (in saga::url name,
                                   out boolean exists);
  Inputs:   name:                 name to be tested for
                                   existence
+  InOuts:   -
  Outputs:  exists:               boolean indicating existence
                                   of name
+  PreCond:  -
+  PostCond: -
+  Perms:    Query for name.
+            Exec  for name's parent directory.
+            Read  for name's parent directory.
+  Throws:   NotImplemented
+            IncorrectURL
+            BadParameter
+            IncorrectState
+            PermissionDenied
+            AuthorizationFailed
+            AuthenticationFailed
+            Timeout
+            NoSuccess
!  Notes:    - if 'name' can be parsed as URL, but contains
!            an invalid entry name, an 'BadParameter'
-            exception is thrown.
-            - note that no exception is thrown if the entry
!            does not exist - the method just returns
-            'false' in this case.
-            - similar to 'test -e' as defined by POSIX.

```

```

- is_dir
!   Purpose:  tests name for being a directory
      Format:  is_dir          (in  saga::url name,
-                               in  int    flags = None,
                               out boolean test);
      Inputs:  name:          name to be tested
-             flags:          flags for operation
+   InOuts:   -
      Outputs: test:          boolean indicating if name
                               is a directory
+   PreCond:  -
+   PostCond: -
+   Perms:    Query for name.
+             Exec  for name's parent directory.
+             Read  for name's parent directory.
+   Throws:   NotImplemented
              IncorrectURL
              BadParameter
              DoesNotExist
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
      Notes:  - returns true if the instance represents
              a directory entry, false otherwise
-             - all notes to the ns_ntry::is_dir() method apply.
!             - the default flags are 'None' (0).
!             - if 'name' can be parsed as URL, but contains
              an invalid entry name, an 'BadParameter'
              exception is thrown.
              - if 'name' is a valid entry name but the entry
!             does not exist, a 'DoesNotExist' exception is
              thrown.
-             - if the entry identified by 'name' is a symbolic
-             link and the 'Dereference' flag is given, the
-             link target is tested.  If the flag is not
-             given, the method returns 'false'.
+             - similar to 'test -d' as defined by POSIX.
-             - similar to 'test ! -d' as defined by POSIX.

- is_entry

```

```

!   Purpose:  tests name for being an ns_entry
           Format:  is_entry          (in  saga::url name,
-                                     in  int      flags = None,
                                     out boolean test);

           Inputs:  name:             name to be tested
-                 flags:             flags for operation
+   InOuts:  -
           Outputs: test:             boolean indicating if name
                                     is a non-directory entry

+   PreCond:  -
+   PostCond: -
+   Perms:    Query for name.
+             Exec  for name's parent directory.
+             Read  for name's parent directory.
+   Throws:   NotImplemented
+             IncorrectURL
+             BadParameter
+             DoesNotExist
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess

           Notes:  - all notes to the ns_ntry::is_entry() method
-                   apply.
-                   - the default flags are 'None' (0).
!                   - if 'name' can be parsed as URL, but contains
!                   an invalid entry name, a 'BadParameter'
-                   exception is thrown.
-                   - if 'name' is a valid entry name but the entry
!                   does not exist, a 'DoesNotExist' exception is
-                   thrown.
-                   - if the entry identified by 'name' is a symbolic
-                   link and the 'Dereference' flag is given, the
-                   link target is tested. If the flag is not
-                   given, the method returns 'false'.

+              DoesNotExist
+              PermissionDenied
+              AuthorizationFailed
+              AuthenticationFailed
+              Timeout
+              NoSuccess
+      Notes:   - all notes to the ns_ntry::is_link() method
+               - apply.
-               - the default flags are 'None' (0).
!               - if 'name' can be parsed as URL, but contains
!               an invalid entry name, a 'BadParameter'
+               exception is thrown.
+               - if 'name' is a valid entry name but the entry
!               does not exist, a 'DoesNotExist' exception is
+               thrown.
-               - if the entry identified by 'name' is a symbolic
-               link and the 'Dereference' flag is given, the
-               link target is tested. If the flag is not
-               given, the method returns 'false'.
-               - similar to 'test -L' as defined by POSIX.

- read_link
  Purpose: returns the name of the link target
  Format:  read_link          (in  saga::url name,
+                               out saga::url link);
+      Inputs:  name:          name to be resolved
+      InOuts:  -
+      Outputs: link:          resolved name
+      PreCond: -
+      PostCond: -
+      Perms:   Query for name.
+              Exec  for name's parent directory.

```

```

+      Read  for name's parent directory.
      Throws:  NotImplemented
               IncorrectURL
               BadParameter
               DoesNotExist
               IncorrectState
               PermissionDenied
               AuthorizationFailed
               AuthenticationFailed
               Timeout
               NoSuccess
      Notes:   - all notes to ns_entry::read_link() apply
!             - if 'name' can be parsed as URL, but contains
!             an invalid entry name, a 'BadParameter'
               exception is thrown.
               - if 'name' does not exist, a 'DoesNotExist'
               exception is thrown.

```

Iterate over large directories:

```

-----

- get_num_entries
  Purpose:  gives the number of entries in the directory
  Format:   get_num_entries    (out int    num);
  Inputs:   -
+  InOuts:  -
  Outputs:  num:                number of entries in the
                                directory
+  PreCond:  -
+  PostCond: -
+  Perms:    Query for cwd.
+            Exec  for cwd.
+            Read  for cwd.
+  Throws:   NotImplemented
               IncorrectState
               PermissionDenied
               AuthorizationFailed
               AuthenticationFailed
               Timeout
               NoSuccess
  Notes:    - at the time of using the result of this call,
              the actual number of entries may already have
              changed (no locking is implied)
              - vaguely similar to 'opendir'/'readdir' (2) as

```

defined by POSIX.

```

- get_entry
  Purpose: gives the name of an entry in the directory
           based upon the enumeration defined by
           get_num_entries
  Format:  get_entry          (in int          entry,
                              out saga::url name);
  Inputs:  entry:             index of entry to get
+ InOuts:  -
+ Outputs: name:              name of entry at index
+ PreCond: -
+ PostCond: -
+ Perms:   Query for cwd.
+          Exec  for cwd.
+          Read  for cwd.
+ Throws:  NotImplemented
           IncorrectState
           DoesNotExist
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:   - '0' is the first entry
           - there is no sort order implied by the
             enumeration, however an underlying
             implementation MAY choose to sort the entries
           - subsequent calls to get_entry and/or
             get_num_entries may return inconsistent data,
             i.e. no locking or state tracking is implied.
             In particular, an index may be invalid - a
             'DoesNotExist' exception is then thrown (not a
             'BadParameter' exception).
           - vaguely similar to 'opendir'/'readdir' (2) as
             defined by POSIX.

-
- Methods for managing access control lists:
- -----
-
- - set_acl
-   Purpose: set access control list for this entry
-   Format:  set_acl          (in string  name,
-                              in string  dn,

```

```

-                                     in int      acl,
-                                     in int      flags = None);
-
-   Inputs:  name:      entry to set ACLs for
-            dn:        DN to set ACLs for
-            flags:     flags defining the operation
-                                     modus
-
-   Outputs: -
-   Perms:   -
-   Throws:  NotImplemented
-            IncorrectURL
-            BadParameter
-            DoesNotExist
-            IncorrectState
-            PermissionDenied
-            AuthorizationFailed
-            AuthenticationFailed
-            Timeout
-            NoSuccess
-
-   Notes:   - all notes to the ns_entry::set_acl() method
-             apply.
-             - the default flags are 'None' (0).
-             - if 'name' can be parsed as URL, but contains
-               an invalid entry name, a 'BadParameter'
-               exception is thrown.
-             - if 'name' is a valid entry name but the entry
-               does not exist, a 'DoesNotExist' exception is
-               thrown.
-
-
-
-
-   - get_acl
-   Purpose: get access control list for this entry
-   Format:  get_acl      (in string  name,
-                         in string  dn,
-                         in int     flags = None,
-                         out int    acl);
-
-   Inputs:  dn:          entry to get ACLs for
-            dn:          DN to get ACLs for
-            flags:       flags defining the operation
-                         modus
-
-   Outputs: acl:         OR'ed ACLs set on the
-                         entity, for the specified dn
-
-   Perms:   -
-   Throws:  NotImplemented
-            IncorrectURL
-            BadParameter
-            DoesNotExist

```

```

-         IncorrectState
-         PermissionDenied
-         AuthorizationFailed
-         AuthenticationFailed
-         Timeout
-         NoSuccess
-     Notes:
-         - all notes to the ns_entry::get_acl() method
-           apply.
-         - the default flags are 'None' (0).
-         - if 'name' can be parsed as URL, but contains
-           an invalid entry name, a 'BadParameter'
-           exception is thrown.
-         - if 'name' is a valid entry name but the entry
-           does not exist, a 'DoesNotExist' exception is
-           thrown.
-
-
- - list_dn
-     Purpose: list all DN's for which ACLs are set.
-     Format:  list_dn          (in  string name,
-                               in  int   flags = None,
-                               out array<string> dn);
-     Inputs:  name:           entry to list DNs for operation
-                          flags: flags defining the operation
-     Outputs: dn:             list of DNs for which ACLs
-                               are set on the entry
-
-     Perms:   -
-     Throws:  NotImplemented
-             IncorrectURL
-             BadParameter
-             DoesNotExist
-             IncorrectState
-             PermissionDenied
-             AuthorizationFailed
-             AuthenticationFailed
-             Timeout
-             NoSuccess
-     Notes:
-         - all notes to the ns_entry::get_dn() method
-           apply.
-         - the default flags are 'None' (0).
-         - if 'name' can be parsed as URL, but contains
-           an invalid entry name, a 'BadParameter'
-           exception is thrown.
-         - if 'name' is a valid entry name but the entry
-           does not exist, a 'DoesNotExist' exception is
-           thrown.
-

```

-

Management of name space entries:

```

- copy
  Purpose: copy the entry to another part of the name space
  Format:  copy          (in saga::url source,
                        in saga::url target,
                        in int    flags = None);

  Inputs:  source:      name to copy
           target:      name to copy to
           flags:       flags defining the operation
                        modus

+   InOuts: -
+   Outputs: -
+   PreCond: -
+   PostCond: - an identical copy of source exists at target.
+               - 'Owner' of target is the id of the context
+                 used to perform the operation if target gets
+                 created.
+   Perms:   Query for source.
+             Exec for source's parent directory.
+             Query for target.
+             Query for target's parent directory.
+             Exec for target's parent directory.
+             Write for target
+               if target does exist.
+             Write for target's parent directory
+               if target does not exist.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           AlreadyExists
+           DoesNotExist
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess

  Notes:    - all notes to the ns_entry::copy() method
            apply.
!           - the default flags are 'None' (0).
!           - if 'name' can be parsed as URL, but contains

```

```

!           an invalid entry name, a 'BadParameter'
             exception is thrown.
- if 'name' is a valid entry name but the entry
!           does not exist, a 'DoesNotExist' exception is
             thrown.

- link
!   Purpose: create a symbolic link from the target entry to
!           the source entry so that any reference to the
             target refers to the source entry
   Format:  link           (in saga::url source,
                           in saga::url target,
                           in int    flags = None);
   Inputs:  source:        name to link
             target:        name to link to
             flags:         flags defining the operation
                           modus

+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - a symbolic link to source exists at target.
+               - 'Owner' of target is the id of the context
+                 used to perform the operation if target gets
+                 created.
+   Perms:   Query for source.
+             Exec  for source's parent directory.
+             Query for target.
+             Query for target's parent directory.
+             Exec  for target's parent directory.
+             Write for target
+                 if target does exist.
+             Write for target's parent directory
+                 if target does not exist.
+   Throws:  NotImplemented
+             IncorrectURL
+             BadParameter
+             AlreadyExists
+             DoesNotExist
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
   Notes:    - all notes to the ns_entry::link() method

```

```

+         apply.
+         - if the 'Recursive' flag is defined, the source
+           is recursively linked if it is a directory;
+           otherwise this flag is ignored.
+         - if the 'Dereference' flag is specified, the
+           method applies to the link target of source.
+           The flag causes a 'BadParameter' exception if
+           source is not a link.
+         - if the the target already exists, the
+           'Overwrite' flag must be specified, otherwise
+           an 'AlreadyExists' exception is thrown.
+         - the default flags are 'None' (0).
+         - other flags are not allowed on this method,
+           and cause a 'BadParameter' exception.
+         - if 'source' can be parsed as URL, but contains
+           an invalid entry name, a 'BadParameter'
+           exception is thrown.
+         - if 'source' is a valid entry name but the entry
+           does not exist, a 'DoesNotExist' exception is
+           thrown.

- move
  Purpose:  rename source to target, or move source to
!           target if target is a directory.
  Format:   move           (in saga::url source,
                           in saga::url target,
                           in int    flags = None);

  Inputs:   source:        name to move
            target:        name to move to
            flags:         flags defining the operation
                           modus

+  InOuts:   -
+  Outputs:  -
+  PreCond:  -
+  PostCond: - an identical copy of source exists at target.
+             - source is removed.
+             - 'Owner' of target is the id of the context
+               used to perform the operation if target gets
+               created.
+  Perms:    Query for source.
+            Write for source.
+            Exec for source's parent directory.
+            Write for source's parent directory.
+            Query for target.
+            Exec for target's parent directory.

```

```

+           Write for target
+             if target does exist.
+           Write for target's parent directory

!        an invalid entry name, a 'BadParameter'
!        exception is thrown.
!        - similar to 'mkdir' (2) as defined by POSIX.

- open_dir
Purpose: creates a new ns_directory instance
Format:  open_dir          (in  saga::url name,
                            in int    flags = None,
                            out ns_directory dir);
Inputs:  name:             directory to open

```

```

                                flags:                flags defining the operation
                                                    modus
+   InOuts:  -
+   Outputs: dir:                opened directory instance
+   PreCond: -
+   PostCond: - the session of the returned instance is that of
+               the calling instance.
+               - 'Owner' of name is the id of the context
+                 used to perform the operation if name gets
+                 created.
+               - the namespace directory is created if it
+                 does not yet exist, and the Create is set.
+   Perms:   Exec  for name's parent directory.
+             Write for name's parent directory if Create is set.
+             Write for name if Write is set.
+             Read  for name if Read  is set.
+   Throws:  NotImplemented
+             IncorrectURL
+             BadParameter
+             AlreadyExists
+             DoesNotExist
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
+   Notes:   - the cwd of the new dir object instance is set
+             to 'name'
!           - a 'DoesNotExist' exception is thrown if 'name'
+             does not exist and the 'Create' flag is not
+             given.
!           - a 'AlreadyExist' exception is thrown if 'name'
+             does exist and the 'Create' flag and the
+             'Exclusive' flag are given.
+           - no exception is thrown if 'name' does exist and
+             the 'Create' flag is given, and the 'Exclusive'
+             flag is not given.
!           - if the 'Create' flag is given, all notes to the
+             ns_directory::make_dir() method apply.
!           - the default flags are 'None' (0).
+           - other flags are not allowed on this method,
+             and cause a 'BadParameter' exception.
!           - 'name' is always deeply dereferenced, however,
+             the cwd is still set to 'name', and not to the
+             value of the link target.

```

```

+         - parent directories are created on the fly if
+         the 'CreateParents' and 'Create' flag are both
+         given, if they don't exist.
!         - if 'name' can be parsed as URL, but contains
!         an invalid directory name, a 'BadParameter'
          exception is thrown.
-         - in the asynchronous case, the resulting
-         directory instance is passed as reference. If
-         that directory instance belongs to the default
-         SAGA session, its session will be changed to
-         the current session. If that directory
-         instance session is not the default session,
-         and is different from the current session,
-         an 'IncorrectSession' exception is thrown.

- open
  Purpose: creates a new ns_entry instance
  Format:  open                                (in saga::url name,
                                              in int      flags = None,
                                              out ns_entry entry);

  Inputs:  name:                             entry
          flags:                             flags defining the operation
                                              modus

+  InOuts:  -
  Outputs:  entry:                             opened entry instance
+  PreCond:  -
+  PostCond: - the session of the returned instance is that
+              of the calling instance.
+              - 'Owner' of name is the id of the context
+                used to perform the operation if name gets
+                created.
+              - the namespace entry is created if it does not
+                yet exist, and the CREATE flag is specified.
+  Perms:    Exec for name's parent directory.
+            Write for name's parent directory if Create is set.
+            Write for name if Write is set.
+            Read for name if Read is set.
  Throws:   NotImplemented
            IncorrectURL
            BadParameter
            AlreadyExists
            DoesNotExist
            IncorrectState
            PermissionDenied
            AuthorizationFailed

```

AuthenticationFailed

Timeout

NoSuccess

- Notes:
- a 'BadParameter' exception is thrown if 'name' points to a directory, or is an invalid entry name.
 - a 'DoesNotExist' exception is thrown if 'name' does not exist, and the 'Create' flag is not given.
 - a 'AlreadyExists' exception is thrown if 'name' does exist, and the 'Create' and 'Exclusive' flags are given.
 - 'name' is always deeply dereferenced, the cwd, however, is not changed to the link targets cwd.
 - parent directories are created on the fly if the 'CreateParents' and 'Create' flag are both given, if they don't exist.
 - the entry is locked on open if the 'Lock' flag is given. If the entry is already in a locked state, the open will fail and a descriptive error will be issued. If a entry is opened in locked mode, any other open on that entry MUST fail with a 'NoSuccess' exception if the 'Lock' flag is given. Note that a entry can be opened in unlocked mode, and then in locked mode, without an error getting raised. The application programmer must take precautions to avoid such situations. The lock will get removed on destruction of the entry object, and also on close. If an implementation does not support locking, a descriptive 'BadParameter' exception MUST get thrown if the 'Lock' flag is given. Read-locks and Write-locks are not distinguished.
 - the default flags are 'None' (0).
 - other flags are not allowed on this method, and cause a 'BadParameter' exception.
 - in the asynchronous case, the resulting entry instance is passed by reference. If that entry instance belongs to the default SAGA session, its session will be changed to the current session. If that entry instance session is not the default session, and is different from the current session, an 'IncorrectSession' exception is thrown.

+   - permissions_allow
+   Purpose: enable a permission
+   Format:  permissions_allow    (in string target,
+                                in string id,
+                                in int    perm,
+                                in int    flags = None);
+   Notes:   - the syntax and semantics of this call is
+             identical to its URL based counterpart.
+             - the 'source' string can contain wildcards, as
+             described above.
+             - on error conditions on any of the expanded
+             list of source entries, the respective error
+             described in the URL version of the method is
+             thrown - the state of the operations on the
+             other elements of the expanded entry list is
+             undefined.
+
+   - permissions_deny
+   Purpose: disable a permission flag
+   Format:  permissions_deny    (in string target,
+                                in string id,
+                                in int    perm,
+                                in int    flags = None);
+   Notes:   - the syntax and semantics of this call is
+             identical to its URL based counterpart.
+             - the 'source' string can contain wildcards, as
+             described above.
+             - on error conditions on any of the expanded
+             list of source entries, the respective error
+             described in the URL version of the method is
+             thrown - the state of the operations on the

```

```

+           other elements of the expanded entry list is
+           undefined.

```

4.2.4 Examples:

Code Example

```

1  More examples are given in the File and Logical_File packages.
2
3  Example: provide recursive directory listing for a given
4          directory
5
6  Note:   - check for '.' and '..' recursion are left as an
7           exercise to the reader.
8           - string operations and printf statements are
9           obviously simplified.
10
11  +-----+
12  // c++ example
13  std::string indent (int indent)
14  {
15      std::string s = " ";
16
17      for (int i = 0; i < indent; i++, s += " ");
18
19      return (s);
20  }
21
22  void list_dir (saga::url url,
23                int      indent = 0)
24  {
25      try
26      {
27          // create directory and iterate over entries
28          saga::ns_dir dir (url);
29
30          printf ("\n%s ---> %s\n", indent (indent), url.get_url ());
31
32          for ( int i = 0; i < dir.get_num_entries (); i++ )
33          {
34              char   type = '?';
35              string info = "";
36
37              // get name of next entry
38              saga::url name = dir.get_entry (i);
39
40              // get type and other infos
41              if ( dir.is_link (name) )

```

```

42     {
43         // check where link points to
44         if (dir.exists(dir.read_link (name))){info=" ---> ";}
45         else                                     {info=" -|-> ";}
46         info += dir.read_link (name);
47         type = 'l';
48     }
49     else if (dir.is_entry(name)){ type = 'f';           }
50     else if (dir.is_dir  (name)){ type = 'd'; info = "/";}
51
52     printf ("%s > %3d - %s - %s%s\n",
53             indent (indent), i + 1,
54             type, name.get_cstr (), info);
55
56     // recursion on directories
57     if ( dir.is_dir (name) )
58     {
59         list_dir (name, indent++);
60     }
61 }
62
63 printf ("\n%s <--- %s\n", indent (indent), url.get_url ());

106
107          f_2.write ("data", 4);
108      }
109  }
```

4.3 SAGA File Management

The ability to access the contents of files regardless of their location is central to many of the SAGA use cases. This section addresses the most common operations detailed in these use cases.

It is *important* to note that interactions with files as opaque entities (i.e. as entries in file name spaces) are covered by the `namespace` package. The classes presented here supplement the `namespace` package with operations for the reading and writing of the *contents* of files. For all methods, the descriptions and notes of the equivalent methods in the `namespace` package apply if available, unless noted here otherwise.

The described classes are *syntactically* and semantically POSIX oriented [21, 22, 23]. *Executing* large numbers of simple POSIX-like remote data access operations *is*, however, prone to latency related performance problems. To allow for efficient implementations, the presented API borrows ideas from GridFTP and other specifications which are widely used for remote data access. These *extensions* should be seen as just that: optimizations. Implementations of this package MUST implement the POSIX-like `read()`, `write()` and `seek()` methods, and MAY implement the additional optimized methods (a 'NotImplemented' *exception* MUST be thrown if these are not implemented). The optimizations included here are:

Scattered I/O Scattered I/O operations are already defined by POSIX, as `readv()` and `writelv()`. Essentially, these methods represent vector versions of the standard POSIX `read()/write()` methods; the *arguments* are, *basically*, vectors of instructions *to execute*, and buffers to operate *upon*. In other words, `readv()` and `writelv()` can be regarded as specialized bulk methods, which cluster multiple I/O operations into a single operation. Advantage of such an approach are that it is easy to implement, is very close to the original POSIX I/O in semantics, and in some cases even very fast. Disadvantages are that for many small I/O operations (a common occurrence in SAGA use cases), the description of the I/O operations can be larger than the sent, returned or received data.

Pattern-Based I/O (FALLS) One approach to address the bandwidth limitation of scattered I/O is to describe the required I/O operations at a more abstract level. Regularly repeating patterns of binary data can be described by the so-called 'Family of Line Segments' (FALLS) [14]. The pattern-based I/O routines in SAGA use such descriptions to reduce the bandwidth limitation of scattered I/O. The *advantage* of such an approach is that it targets very common data access patterns (at least those very commonly found in SAGA use cases). The disadvantages are that FALLS is a paradigm not widely known or used, and that FALLS is by definition, limited to regular patterns of data,

and hence is inefficient for more randomized data access.

FALLS (FAMiLy of Line Segments) were originally introduced for transformations in parallel computing. There is also a parallel filesystem which uses FALLS to describe the file layout. They can be used to describe regular subsets of arrays with a very compact syntax.

FALLS pattern are formed as 5-tuples: "(from,to,stride,rep,(pat))". The **from** element defines the starting offset for the first pattern unit, **to** defines the finishing offset of the first pattern unit, **stride** defines the distance between consecutive pattern units (begin to begin), and **rep** defines the number of repetitions of the pattern units. The optional 5th element **pat** allows to defines nested **patterns**, where the internal pattern defines the unit the outer pattern is applied to (by default that is one byte). As an example: the following FALLS describe the highlighted elements of the matrix in Fig 5: "(0,17,36,6,(0,0,2,6))": the inner pattern describes a pattern unit of one byte length (from 0 to 0), with a distance of 2 to the next application, and 6 repetitions. These are the 6 bytes per line which are marked *red*. The outer pattern defines the repeated application of the inner pattern, starting at 0, ending at 17 (end of line), distance of 36 (to begin of next but one line), and repetition of 6.

Figure 5: The highlighted elements are defined by "(0,17,36,6,(0,0,2,6))".

Extended I/O GridFTP (which was designed for a similar target domain) introduced an additional remote I/O paradigm, that of Extended I/O operations.

In essence, the Extended I/O paradigm allows the formulation of I/O requests using custom strings, which are not interpreted on the client but on the server side; these can be expanded to **arbitrarily** complex sets of I/O operations. The type of I/O request encoded in the string is called **mode**. A server may support one or many of these extended I/O modes. Whereas the approach is very flexible and powerful and has proven its usability in GridFTP, a disadvantage is that it requires very specific infrastructure to function, i.e. it requires a remote server instance which can interpret opaque client requests. Additionally, no client side checks or optimizations on the I/O requests are possible. Also, the application programmer needs to estimate the size of the data to be returned in advance, which in some cases is very difficult.

The three described operations have, if compared to each other, increasing semantic flexibility, and are increasingly powerful for specific use cases. However, they are also increasingly difficult to implement and support in a generic fashion. It is up to the SAGA implementation and the specific use cases, to determine the level of I/O abstraction that serves the application best and that can be best supported in the target environment.

4.3.1 Specification

```

package saga.file

}

```

4.3.2 Specification Details

Enum flags

*The **flags** enum is inherited from the **namespace** package. A number of file specific flags are added to it. All added flags are used for the opening of **file** and **directory** instances, and are not applicable to the operations inherited from the **namespace** package.*

Truncate

Upon opening, the file is truncated to length 0, i.e. a following `read()` operation will never find any data in the file. That flag does not apply to directories.

Append

Upon opening, the file pointer is set to the end of the file, i.e. a following `write()` operation will extend the size of the file. That flag does not apply to directories.

Read

The file or directory is opened for reading – that does not imply the ability to write to the file or directory.

Write

The file or directory is opened for writing – that does not imply the ability to read from the file or directory.

ReadWrite

The file or directory is opened for reading and writing.

Binary

Some operating systems (notably windows based systems) distinguish between binary and non-binary modes – this flag mimics that behaviour.

Class iovec

The `iovec` class inherits the `saga::buffer` class, and three additional state attributes: `offset`, `len_in` and `len_out` (with the latter one being read-only). With that addition, the new class can be used very much the same way as the `iovec` structure defined by POSIX for `readv/writev`, with the buffer `len_in` being interpreted as the POSIX `iov_len`, i.e. the number of bytes to read/write.

If `len_in` is not specified, that length is set to the size of the buffer. It is a `BadParameter` error if `len_in` is specified to be larger than size, for application managed buffers (see Section 3.4 for details on buffer memory management). Before an `iovec` instance is used, it's `len_in` MUST be set to a non-zero value; otherwise it's use will cause a `BadParameter` exception.

After a `read_v()` or `write_v()` operations completes, `len_out` will report the number of bytes read. Before completion, the SAGA implementation MUST report `len_out` to be -1.

-
- + - CONSTRUCTOR
 - + Purpose: create an `iovec` instance

```

+   Format:   CONSTRUCTOR      (in  array<byte> data   = "",
+                               in  int      size    = -1,
+                               in  int      offset   = 0,
+                               in  int      len_in   = size,
+                               out iovec    obj);
+   Inputs:   type:            data to be used
+               size:          size of data to be used
+               offset         offset for I/O operation
+               len_in:        number of bytes to read
+                               or write on read_v/write_v
+   InOuts:   -
+   Outputs:  buffer:          the newly created iovec
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   BadParameter
+             NoSuccess
+   Notes:    - all notes from the buffer CONSTRUCTOR apply.
+               - if len_in is larger than size, and size is
+                 not given as -1, a 'BadParameter' exception
+                 is thrown.
+
+ - DESTRUCTOR
+   Purpose:  destroy an iovec instance
+   Format:   DESTRUCTOR      (in  iovec obj);
+   Inputs:   obj:            the iovec to destroy
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   -
+   Notes:    - all notes from the buffer DESTRUCTOR apply.
+
+ - set_offset
+   Purpose:  set offset
+   Format:   set_offset      (in  int  offset);
+   Inputs:   offset:         value for offset
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   BadParameter
+   Notes:    - if offset is smaller than zero, a
+               'BadParameter' exception is thrown.

```

```
+
+ - get_offset
+   Purpose: retrieve the current value for offset
+   Format:  get_offset          (out int   offset);
+   Inputs:  -
+   InOuts:  -
+   Outputs: offset:              value of offset
+   PreCond: -
+   PostCond: -
+   Perms:   -
+   Throws:  -
+   Notes:   -
+
+ - set_len_in
+   Purpose: set len_in
+   Format:  set_len_in          (in int   len_in);
+   Inputs:  len_in:              value for len_in
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: -
+   Perms:   -
+   Throws:  BadParameter
+   Notes:   - if len_in is larger than size, and size is
+               not set to -1, a 'BadParameter' exception
+               is thrown.
+
+ - get_len_in
+   Purpose: retrieve the current value for len_in
+   Format:  get_len_in          (out int   len_in);
+   Inputs:  -
+   InOuts:  -
+   Outputs: len_in:              value of len_in
+   PreCond: -
+   PostCond: -
+   Perms:   -
+   Throws:  -
+   Notes:   -
+
+ - get_len_out
+   Purpose: retrieve the value for len_out
+   Format:  get_len_out          (out int   len_out);
+   Inputs:  -
+   InOuts:  -
+   Outputs: len_out:              value of len_out
+   PreCond: -
```

```

+   PostCond: -
+   Perms:    -
+   Throws:   -
+   Notes:    - len_out reports the number of bytes read
+               or written in a completed read_w or write_w
+               operation.
+               - before completion of the operation, the
+               returned value is -1.
+               - for implementation managed memory, the
+               value of len_out is always the same as
+               for size.

```

Class file

This class represents an open file descriptor for read/write operations on a physical file. Its concept is similar to the file descriptor returned by the `open (2)` call in POSIX.

Several In language bindings where this is appropriate, *several* methods can return error codes indicating failure, instead of always raising an exception. These error codes are, as described in *the saga error section* [Section 3.1](#), defined as POSIX `errno` values. These codes SHOULD be used in identical situations as described in POSIX. The calls which can use return error codes are documented.

```

- CONSTRUCTOR
  Purpose:  create the obj
!   Format:  CONSTRUCTOR      (in session s,
                              in saga::url name,
                              in int      flags = Read,
                              out file    obj)
!   Inputs:  s:               session to associate the
!                               object with
                              name:      location of file
                              flags:     mode for opening
+   InOuts:  -
+   Outputs: obj:             the newly created object
+   PreCond: -
+   PostCond: - the file is opened.
+               - 'Owner' of target is the id of the context
+               use to perform the operation, if the file
+               gets created.
+   Perms:   Exec for parent directory.

```

```

+           Write for parent directory if Create is set.
+           Write for name if Write is set.
+           Read  for name if Read  is set.
    Throws:  NotImplemented
             IncorrectURL
             BadParameter
             AlreadyExists
             DoesNotExist
-           IncorrectState
             PermissionDenied
             AuthorizationFailed
             AuthenticationFailed
             Timeout
             NoSuccess
    Notes:   - all notes from the directory::open() method
              apply.
!           - the default flags are 'Read' (512).

```

```

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR          (in file      obj)
  Inputs:   obj:                the object to destroy
+  InOuts:   -
  Outputs:   -
+  PreCond:   -
+  PostCond: - the file is closed.
+  Perms:     -
  Throws:    -
  Notes:     - the semantics of the inherited destructors
              apply

```

additional inspection methods:

```

- get_size
  Purpose:  returns the number of bytes in the file
  Format:   get_size          (out int      size);
  Inputs:   -
+  InOuts:   -
  Outputs:  size:              number of bytes in the file
+  PreCond:   -
+  PostCond:  -
+  Perms:     Query
  Throws:    NotImplemented

```

```

-      IncorrectURL
-      BadParameter
      IncorrectState
      PermissionDenied
      AuthorizationFailed
      AuthenticationFailed
      Timeout
      NoSuccess
Notes:  - similar to the 'st_size' field from 'stat' (2)
        as defined by POSIX

POSIX-like I/O methods:
-----

- read
  Purpose: reads up to len_in bytes from the file into
           the buffer.
-   Format: read          (in   array<byte> buffer,
+   Format: read          (inout buffer      buf,
!                               in   int      len_in = -1,
                               out  int      len_out);

  Inputs:  len_in:        number of bytes to be read
!   InOuts: buf:          buffer to read data into
  Outputs: len_out:       number of bytes successfully
                               read

+   PreCond: -
+   PostCond: - the data from the file are available in the
+               buffer.
+   Perms:    Read
  Throws:    NotImplemented
            BadParameter
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
!   Notes:    - the actual number of bytes read into buffer
               is returned in len_out. It is not an error
               to read less bytes than requested, or in fact
               zero bytes, e.g. at the end of the file.
               - errors are indicated by returning negative
               values for len_out, which correspond to
!               negatives of the respective POSIX ERRNO error
               code.

```

```

- the file pointer is positioned at the end of
  the byte area successfully read during this
  call.
!
! - the given buffer must be large enough to
!   store up to len_in bytes, or managed by the
!   implementation - otherwise a 'BadParameter'
!   exception is thrown.
+
+ - the notes about memory management from the
  buffer class apply.
!
! - if the file was opened in write-only mode (i.e.
!   no 'Read' or 'ReadWrite' flag was given), this
!   method throws an 'PermissionDenied' exception.
!
! - if len_in is smaller than 0, or not given,
!   the buffer size is used for len_in.
!   If that is also not available, a
!   'BadParameter' exception is thrown.
!
- similar to read (2) as specified by POSIX

- write
  Purpose: writes up to len_in bytes from buffer into
           the file at the current file position.
-   Format: write      (in array<byte> buffer,
+   Format: write      (in buffer      buf,
!                       in int         len_in = -1,
!                       out int        len_out);

  Inputs:  len_in:      number of bytes to write
!          buf:         buffer to write data from
+
  InOuts:  -
  Outputs: len_out:     number of bytes successfully
                       written

+   PreCond: -
+   PostCond: - the buffer data are written to the file.
+   Perms:   Write
  Throws:   NotImplemented
           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess

  Notes:    - errors are indicated by returning negative
             values for len_out, which correspond to
             negatives of the respective POSIX ERRNO error
             code.

```

```

- the file pointer is positioned at the end
  of the byte area written during this call.
!
- if the file was opened in read-only mode (i.e.
!   no 'Write' or 'ReadWrite' flag was given), this
!   method throws an 'PermissionDenied' exception.
+
- the given buffer must hold enough data to
+   write - otherwise, only the available data
+   will be written, and len_out will be set
+   to the number of bytes written.
+
- the notes about memory management from the
+   buffer class apply.
!
- if len_in is smaller than 0, or not given,
!   the buffer size is used for len_in.
!   If that is also not available, a
!   'BadParameter' exception is thrown.
- if data are written beyond the current end of
  file, the intermediate gap is filled with '\0'
  bytes.
- similar to write (2) as specified by POSIX

- seek
  Purpose: reposition the file pointer
  Format:  seek          (in int      offset,
                        in seek_mode whence,
                        out int      position);
  Inputs:  offset:      offset in bytes to move
                        pointer
            whence:      offset is relative to
                        'whence'
+
  InOuts:  -
  Outputs: position:      position of pointer after
                        seek
+
  PreCond: -
+
  PostCond: - the file pointer is moved to the new position.
+           - following read() or write() operations use
+             that position.
+
  Perms:   Read or Write.
  Throws:  NotImplemented
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
  Notes:   - seek repositions the file pointer for

```

- subsequent read, write and seek calls.
- initially (after open), the file pointer is positioned at the beginning of the file, unless the 'Append' flag was given - then the initial position is the end of the file.
- the repositioning is done relative to the position given in 'Whence', so relative to the 'Begin' or 'End' of the file, or to the 'Current' position.
- errors are indicated by returning negative values for len_out, which correspond to negatives of the respective POSIX ERRNO error code.
- the file pointer can be positioned after the end of the file without extending it.
- the given offset can be positive, negative, or zero.
- note that a subsequent read at or behind the end of file returns no data.
- similar to lseek (2) as specified by POSIX.

Scattered I/O methods:

- read_v
 - Purpose: gather/scatter read
 - ! Format: read_v (inout array<iovec> iovecs);
 - + Inputs: -
 - ! InOuts: iovecs: array of iovec structs
 - defining start (offset) and
 - length (len_in) of each
 - individual read, the buffer
 - to read into, and integer
 - to store result into
 - (len_out).
 - + Outputs: -
 - + PreCond: -
 - + PostCond: - data from the file are available in the
 - + iovec buffers.
 - + Perms: Read
 - + Throws: NotImplemented
 - BadParameter
 - IncorrectState
 - PermissionDenied
 - AuthorizationFailed

```

AuthenticationFailed
Timeout
NoSuccess
Notes: - the behaviour of each individual read is as
        in the normal read method, and all notes from
        the read() method apply.
!      - an exception MUST be thrown if any of the
        individual reads detects a condition which
        would raise an exception for the normal
        read() method.
+      - the notes about memory management from the
+      buffer class apply.
!      - if for any of the given iovecs no len_in is
!      given, then the buffer size is used as len_in.
!      If that is also not available, a
!      'BadParameter' exception is thrown.
+      - if the file was opened WriteOnly, a
+      'PermissionDenied' exception is thrown.
-      - similar to readv (2) as specified by POSIX

- write_v
  Purpose: gather/scatter write
!   Format: write_v          (inout array<iovec> iovecs);
+   Inputs: -
!   InOuts: iovecs:          array of iovec structs
                                defining start (offset) and
                                length (len_in) of each
                                individual write, and
                                buffers containing the data
                                to write (len_out)

+   Outputs: -
+   PreCond: -
+   PostCond: - the iovec buffer data are written to the file.
+   Perms: Write
  Throws: NotImplemented
          IncorrectState
          BadParameter
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess
Notes: - the behaviour of each individual write is as
        in the normal write method.
!      - an exception MUST be thrown if any of the

```

```

        individual writes detects a condition which
        would raise an exception for the normal write
        method.
+       - the notes about memory management from the
+       buffer class apply.
!       - if for any of the given iovecs no len_in is
!       given, then the buffer size is used as len_in.
!       If that is also not available, a
!       'BadParameter' exception is thrown.
+       - if the file was opened ReadOnly, a
+       'PermissionDenied' exception is thrown.
+       - similar to writev (2) as specified by POSIX

```

Pattern-based I/O methods:

```

-----

- size_p
!   Purpose:  determine the storage size required for a
               pattern I/O operation
               Format:  size_p          (in string pattern,
                                       out int    size);
               Inputs:  pattern:        pattern to determine size for
+   InOutputs: -
               Outputs: size:           size required for I/O
                                       operation with that pattern

+   PreCond:  -
+   PostCond: -
+   Perms:    -
               Throws: NotImplemented
                     BadParameter
+               IncorrectState
                     PermissionDenied
                     AuthorizationFailed
                     AuthenticationFailed
                     Timeout
                     NoSuccess
               Notes:  - the method does, in general, not perform a
                       remote operation, but is intended to help
                       the application programmer to correctly handle
                       pattern-based I/O and associated buffer sizes.
                       - if the pattern cannot be parsed or interpreted,
                         a 'BadParameter' exception is thrown.

- read_p

```

```

        Purpose: pattern-based read
        Format:  read_p      (in   string      pattern,
-                               inout array<byte> buffer,
+                               inout buffer    buf,
                                out   int       len_out);

        Inputs:  pattern:    pattern specification for
                                read operation
!       InOuts:  buf:        buffer to store read data
                                into
        Outputs: len_out:    number of successfully read
                                bytes

+       PreCond: -
+       PostCond: - data from the file are available in the
+                   buffers.
+       Perms:   Read
        Throws:  NotImplemented
                   BadParameter
                   AlreadyExists
-                   DoesNotExist
-                   IncorrectState
                   PermissionDenied
                   AuthorizationFailed
                   AuthenticationFailed
                   Timeout
                   NoSuccess
-       Throws:  BadParameter
        Notes:   - if the pattern cannot be parsed or interpreted,
                   a 'BadParameter' exception is thrown.
                   - all notes for the read() method apply for the
                     individual reads resulting from the
                     interpretation of the pattern.
+                   - an exception MUST be thrown if any of the
+                     individual writes detects a condition which
+                     would raise an exception for the normal write
+                     method.

- write_p
        Purpose: pattern-based read
!       Format:  write_p     (in   string      pattern,
-                               in    array<byte> buffer,
+                               in    buffer    buf,
                                out   int       len_out);

        Inputs:  pattern:    pattern specification for
!                               write operation
!                               buf:        buffer to be written

```

```

+   InOuts:  -
           Outputs: len_out:          number of bytes successfully
                                   written
+   PreCond:  -
+   PostCond: - the buffer data are written to the file.
+   Perms:    Write
+   Throws:   NotImplemented
              BadParameter
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
           Notes: - if the pattern cannot be parsed or interpreted,
                  a 'BadParameter' exception is thrown.
                  - all notes for the write() method apply for the
                    individual writes resulting from the
                    interpretation of the pattern.
+                  - an exception MUST be thrown if any of the
+                    individual writes detects a condition which
+                    would raise an exception for the normal write
+                    method.

```

Extended I/O methods:

```

- modes_e
!   Purpose: list the exetnded modes available in this
              implementation, and/or on server side
           Format: modes_e          (out array<string> emodes);
           Inputs:  -
+          InOuts:  -
           Outputs: emodes:          list of modes available for
                                   extended I/O
+          PreCond: -
+          PostCond: -
+          Perms:   -
           Throws:  NotImplemented
                  IncorrectState
                  PermissionDenied
                  AuthorizationFailed
                  AuthenticationFailed
                  Timeout
                  NoSuccess

```

Notes: - the method does, in general, not perform a remote operation, but is intended to help the application programmer to determine what extended I/O methods are supported by the implementation.

```
+ - size_e
+   Purpose: determine the storage size required for an
+             extended I/O operation
+   Format:  size_e          (in string emode,
+                             (in string spec,
+                               out int   size);
+   Inputs:  emode:          extended mode to use
+             spec:          specification to determine
+                             size for
+   InOuts:  -
+   Outputs: size:           size required for I/O
+                             operation with that
+                             emode/spec
+   PreCond: -
+   PostCond: -
+   Perms:   -
+   Throws:  NotImplemented
+             BadParameter
+             IncorrectState
+             PermissionDenied
+             AuthorizationFailed
+             AuthenticationFailed
+             Timeout
+             NoSuccess
+   Notes:   - the method does, in general, not perform a
+             remote operation, but is intended to help
+             the application programmer to correctly handle
+             extended I/O and associated buffer sizes.
+             - if the specification cannot be parsed or
+               interpreted, a 'BadParameter' exception is
+               thrown.

- read_e
+   Purpose: extended read
+   Format:  read_e          (in string emode,
+                             in string spec,
+                               inout array<byte> buffer,
+                               inout buffer buf,
```

```

                                out  int      len_out);
Inputs:  emode:                extended mode to use
        spec:                specification of read
                                operation
! InOuts: buf:                buffer to store read data
                                into
Outputs: len_out:            number of successfully read
                                bytes
+ PreCond: -
+ PostCond: - data from the file are available in the
+           buffers.
+ Perms:    Read
Throws:    NotImplemented
           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
Notes:     - if the emode is not supported, a 'BadParameter'
            exception is thrown.
            - if the spec cannot be parsed or interpreted,
              a 'BadParameter' exception is thrown.
            - all notes from the read() method apply to the
              individual reads resulting from the
!           interpretation of the emode and spec.
+           - an exception MUST be thrown if any of the
+             individual writes detects a condition which
+             would raise an exception for the normal write
+             method.

- write_e
  Purpose: extended write
  Format:  write_e      (in  string      emode,
                        in  string      spec,
-                        in  array<byte> buffer,
+                        in  buffer      buf,
                        out  int        len_out);
Inputs:  emode:                extended mode to use
        spec:                specification of write
                                operation
!           buf:                buffer to store read data
                                into
+ InOuts: -

```

```

!   Outputs:  len_out:          number of bytes successfully
!                                   written
+   PreCond:  -
+   PostCond: - the buffer data are written to the file.
+   Perms:    Write
+   Throws:   NotImplemented
+               BadParameter
+               IncorrectState
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
+   Notes:    - if the emode is not supported, a 'BadParameter'
+               exception is thrown.
+               - if the spec cannot be parsed or interpreted,
+               a 'BadParameter' exception is thrown.
+               - all notes from the write() method apply to the
+               individual writes resulting from the
+               interpretation of the 'emode' and 'spec'.
+               - an exception MUST be thrown if any of the
+               individual writes detects a condition which
+               would raise an exception for the normal write
+               method.

```

Class directory

```

- CONSTRUCTOR
  Purpose:  open the directory
!   Format:  CONSTRUCTOR      (in session  s,
+                                   in saga::url name,
+                                   in int      flags = Read,
!                                   out directory obj)
!   Inputs:  s:               session to associate the
+                                   object with
+                                   name:       location of directory
+                                   flags:      mode for opening
+   InOuts:  -
!   Outputs: obj:             the newly created object
+   PreCond:  -
+   PostCond: - the directory is opened.
+               - 'Owner' of target is the id of the context

```

```

+           use to perform the operation, if the
+           directory gets created.
+   Perms:   Exec   for parent directory.
+           Write for parent directory if Create is set.
+           Write for name if Write is set.
+           Read  for name if Read  is set.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           AlreadyExists
+           DoesNotExist
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
!   Notes:  - the default flags are 'Read' (512).
+           - the semantics of the inherited constructors
+             apply

```

```

- DESTRUCTOR
  Purpose:  destroy the directory object
!   Format:  DESTRUCTOR      (in  directory obj)
!   Inputs:  obj:            the object to destroy
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - the directory is closed.
+   Perms:   -
+   Throws:  -
+   Notes:   - the semantics of the inherited destructors
+             apply.

```

inspection methods:

```

- get_size
  Purpose:  returns the number of bytes in the file
  Format:   get_size      (in  saga::url name,
+                               in  int      flags = None,
+                               out int      size);
+   Inputs:  name:        name of file to inspect
+           flags:        mode for operation
+   InOuts:  -

```

```

Outputs: size:          number of bytes in the file
+ PreCond: -
+ PostCond: -
  Perms:  Query
  Throws: NotImplemented
          IncorrectURL
          BadParameter
          DoesNotExist
          IncorrectState
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess
Notes:   - if 'name' can be parsed as URL, but contains
          an invalid entry name, a 'BadParameter'
          exception is thrown.
          - if the entry 'name' points to does not exist,
          a 'DoesNotExist' exception is thrown.
          - if the 'name' points to a link and the
          'Dereference' flag is set, the size is
          returned for the link target. If that target
          does not exist, a 'DoesNotExist' exception is
          thrown.
          - the default flags are 'None' (0).
          - other flags are not allowed on this method,
          and cause a 'BadParameter' exception.
          - similar to the 'st_size' field from 'stat' (2)
          as defined by POSIX

- is_file
  Alias:   for is_entry in saga::ns_directory

```

Factory-like methods for creating objects:

```

-----

- open_dir
  Purpose: creates a directory object
  Format:  open_dir          (in  saga::url name,
                             in  int      flags = Read,
                             out directory dir)
  Inputs:  name:             name of directory to open
!          flags:            flags defining operation
                             modus
+ InOuts:  -

```

```

        Outputs:  dir:                opened directory instance
+       PreCond:  -
+       PostCond: - the session of the returned instance is that of
+                   the calling instance.
+                   - 'Owner' of name is the id of the context
+                   used to perform the operation if name gets
+                   created.
+       Perms:    Exec  for name's parent directory.
+                   Write for name's parent directory if Create is set.
+                   Write for name if Write is set.
+                   Read  for name if Read  is set.
+       Throws:   NotImplemented
+                   IncorrectURL
+                   BadParameter
+                   AlreadyExists
+                   DoesNotExist
+                   IncorrectState
+                   PermissionDenied
+                   AuthorizationFailed
+                   AuthenticationFailed
+                   Timeout
+                   NoSuccess
+       Notes:    - all notes from the ns_directory::open_dir()
+                   method apply.
!           - default flags are 'Read' (512).

- open
  Purpose:  creates a new file instance
  Format:   open                (in  saga::url name,
                                in  int      flags = Read,
                                out file     file);
  Inputs:   name:               file to be opened
!           flags:              flags defining operation
                                modus
+       InOuts:  -
+       Outputs: file:           opened file instance
+       PreCond: -
+       PostCond: - the session of the returned instance is that of
+                   the calling instance.
+                   - 'Owner' of name is the id of the context
+                   used to perform the operation if name gets
+                   created.
+       Perms:   Exec  for name's parent directory.
+                   Write for name's parent directory if Create is set.
+                   Write for name if Write is set.

```

```

+      Read  for name if Read  is set.
      Throws:  NotImplemented
               IncorrectURL
               BadParameter
               AlreadyExists
               DoesNotExist
               IncorrectState
               PermissionDenied
               AuthorizationFailed
               AuthenticationFailed
               Timeout
               NoSuccess
      Notes:   - all notes from the ns_directory::open() method
                apply.
                - the file is truncated to length 0 on the open
                  operation if the 'Trunc' flag is given.
                - the file is in opened in append mode if the
                  'Append' flag is given (a seek(0, End) is
                  performed after the open). If the 'Append'
!         flag is not given, the file pointer is
                initially placed at the beginning of the file
                (a seek(0,Start) is performed after the open).
                - the 'Binary' flag is to be silently ignored on
!         systems which do not support it.
+         - at least one of the flags 'Read', 'Write' or
+         'ReadWrite' must be given, otherwise a
+         'BadParameter' exception is thrown.
                - the flag set 'Read | Write' is equivalent to
                the flag 'ReadWrite'.
!         - default flags are 'Read' (512).

```

4.3.3 Examples

Example: open a file. If its size is greater than 10, then read the first 10 bytes into a string, and print it.

Code Example

```

1  // c++ example
2  void head (saga::url url)
3  {
4      try {
5          // get type and other infos
6          saga::file f (url);
7

```

```
8      off_t size = f.get_size ();
9
10     if ( size > 10 )
11     {
12         char    buf[11];
13
14         ssize_t len_out = f.read (saga::buffer (buf));
15
16         if ( 10 == len_out )
17         {
18             std::cout << "head: "
19                       << buffer.get_data ()
20                       << std::endl;
21         }
22     }
23 }
24
25 // catch any possible error - see elsewhere for better
26 // examples of error handling in SAGA
27 catch ( const saga::exception & e )
28 {
29     std::cerr << "Oops! SAGA error: "
30               << e.get_message ()
31               << std::endl;
32 }
33
34 return;
35 }
```

4.4 SAGA Replica Management

This section of the SAGA API describes the interaction with replica systems. Numerous SAGA use cases required replica management functionality in the API – however, only a small number of operation have been requested. The methods described here are hence limited to the creation and maintainance of logical files, replicas, and to search on logical file meta data.

The `saga::logical_file` class implements the `saga::attributes` interface. It is important to realize that this is **intended** to reflect the ability of replica systems to associate meta data with logical files. The SAGA attribute model (string based key/value pairs) can, with all **probability**, only give a crude representation of meta data models used in real world replica systems – however, the definition of a more abstract and comprehensive data model for replica meta data was felt to be outside the scope of a SAGA API definition. Implementations are expected to map the native data model to key/value pairs as well as possible, and MUST document that mapping process (and in particular the supported keys) carefully.

Please note that the interactions with logical files as opaque entities (as entries in logical file name spaces) are covered by the `namespace` package. The interfaces presented here supplement the `namespace` package with operations for operating on entries in replica catalogues.

It is up to the used backend to ensure that multiple replica locations registered on a logical file are indeed identical copies – the SAGA API does not imply any specific consistency model. The SAGA implementation MUST document the consistency model used.

4.4.1 Definitions

Logical File: A *logical file* represents merely an entry in a name space which has (a) an associated set of registered (physical) replicas of that file, and (b) an associated set of meta data describing that logical file. Both sets can be empty. *To access the content of a logical file, a `saga::file` needs to be created with one of the registered replica locations.*

Replica: A *replica* (or *physical file*) is a file which is registered on a logical file. In general, all replicas registered on the same logical *file* are identical. Often, one of these replicas is deemed to be a master **copy** (often **it is** the first replica registered, and/or the only one which can be changed) – that distinction is, however, not visible in the SAGA API.

Logical Directory: A *logical directory* represents a directory entry in the name space of logical files. Several replica system implementations have the notion of *containers*, which, for our purposes, represent directories which can have, just as logical files, associated sets of meta data. In the presented API, logical directories and containers are the same.

Note that the `Truncate`, `Append` and `Binary` flags have no meaning on logical files. The respective enum values for these flags for `saga::files` have been reserved though, for (a) future use, and (b) consistency with the `saga::file` flag values.

The `find()` method of the `saga::logical_directory` class represents a combination of (a) the `find()` method from the `saga::ns_directory` class, and (b) the `find_attributes()` method from the `saga::attributes` interface. The method accepts patterns for meta data matches (*key-pattern and val-pattern* `attr-pattern`) and *a single pattern* for file name matches (`name-pattern`), and returns a list of logical file names *for which both patterns match which match all attr-pattern and the name-pattern (AND semantics)*. The `attr-pattern` are formatted as defined for `find_attribute()` of the `saga::attributes` interface. The `name-pattern` are formatted as defined for the `find()` method of the `saga::ns_directory` class. In general, the allowed patterns are the same as defined as wildcards in the **description** of the SAGA namespace package.

4.4.2 Specification

```
package saga.logical_file
{
    enum flags
    {
!       None           =    0, // same as in namespace::flags
!       Overwrite       =    1, // same as in namespace::flags
!       Recursive       =    2, // same as in namespace::flags
!       Dereference     =    4, // same as in namespace::flags
!       Create          =    8, // same as in namespace::flags

-              in  int              flags = None,
+              in  int              flags = Recursive,
                out array<saga::url> names );
    }
}

```

4.4.3 Specification Details

Enum flags

*The **flags** enum is inherited from the **namespace** package. A number of replica specific flags are added to it. All added flags are used for the opening of **logical_file** and **logical_directory** instances, and are not applicable to the operations inherited from the **namespace** package.*

Read

The logical file or directory is opened for reading – that does not imply the ability to change the logical file or directory.

Write

The logical file or directory is opened for writing – that does not imply the ability to read from the logical file or directory.

ReadWrite

The logical file or directory is opened for reading and writing.

Class logical_file

This class provides *the* means to handle the contents of logical files. These contents consists of strings representing locations of physical files (replicas) associated with the logical file.

```

- CONSTRUCTOR
  Purpose:  create the object
!   Format:  CONSTRUCTOR      (in session    s,
                              in saga::url name,
                              in int        flags = Read,
                              out logical_file obj)
!   Inputs:  s:                session to associate with
!                               the object
                              name:          location of file
                              flags:        mode for opening
+   InOuts:  -
  Outputs:  obj:                the newly created object
+   PreCond:  -
+   PostCond: - the logical_file is opened.
+               - 'Owner' of target is the id of the context
+               use to perform the operation, if the
+               logical_file gets created.
+   Perms:   Exec  for parent directory.
+               Write for parent directory if Create is set.
+               Write for name if Write is set.
+               Read  for name if Read  is set.
+   Throws:  NotImplemented
              IncorrectURL
              BadParameter
              AlreadyExists
              DoesNotExist
-           IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
  Notes:    - the semantics of the inherited constructors
!            and of the logical_directory::open() method
              apply.

```

```

!           - the default flags are 'Read' (512).

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR      (in logical_file  obj)
  Inputs:   obj:            the object to destroy
+  InOuts:   -
+  Outputs:  -
+  PreCond:  -
+  PostCond: - the logical_file is closed.
+  Perms:    -
+  Throws:   -
  Notes:    - the semantics of the inherited destructors
              apply.

manage the set of associated replicas:
-----

- add_location
  Purpose:  add a replica location to the replica set
  Format:   add_location    (in saga::url name);
  Inputs:   name:           location to add to set
+  InOuts:   -
+  Outputs:  -
+  PreCond:  -
+  PostCond: - name is in the list of replica locations for
+              the logical file.
+  Perms:    Write
  Throws:   NotImplemented
              IncorrectURL
              BadParameter
-           ReadOnly
              IncorrectState
              PermissionDenied
              AuthorizationFailed
              AuthenticationFailed
              Timeout
              NoSuccess
  Notes:    - this methods adds a given replica location
              (name) to the set of locations associated with
              the logical file.
              - the implementation MAY choose to interpret the
                replica locations associated with the logical
!           file.  It MAY return an 'IncorrectURL' error

```

```

        indicating an invalid location if it is unable
!       or unwilling to handle that specific locations
!       scheme. The implementation documentation MUST
!       specify how valid replica locations are formed.
        - if 'name' can be parsed as URL, but contains
!       an invalid entry name, a 'BadParameter'
        exception is thrown.
        - if the replica is already in the set, this
!       method does nothing, and in particular MUST
!       NOT raise an 'AlreadyExists' exception
+       - if the logical file was opened ReadOnly, a
+       'PermissionDenied' exception is thrown.

- remove_location
!   Purpose: remove a replica location from the replica set
!   Format:  remove_location (in saga:url name);
!   Inputs:  name:           replica to remove from set
+   InOuts:  -
!   Outputs: -
+   PreCond: -
+   PostCond: - name is not anymore in list of replica
+               locations for the logical file.
+   Perms:   Write
!   Throws:  NotImplemented
!           IncorrectURL
!           BadParameter
!           DoesNotExist
-           ReadOnly
!           IncorrectState
!           PermissionDenied
!           AuthorizationFailed
!           AuthenticationFailed
!           Timeout
!           NoSuccess
!   Notes:   - this method removes a given replica location
!             from the set of replicas associated with the
!             logical file.
!             - the implementation MAY choose to interpret the
!               replica locations associated with the logical
!               file. It MAY return an 'IncorrectURL' error
!               indicating an invalid location if it is unable
!               or unwilling to handle that specific locations
!               scheme. The implementation documentation MUST
!               specify how valid replica locations are formed.
!             - if 'name' can be parsed as URL, but contains

```

```

!           an invalid entry name, a 'BadParameter'
            exception is thrown.
- if the location is not in the set of
  replicas, a 'DoesNotExist' exception is
  thrown.
- if the set of locations is empty after this
  operation, the logical file object is still
  a valid object (see replicate() method
  description).
+
+ - if the logical file was opened ReadOnly, a
  'PermissionDenied' exception is thrown.

- update_location
  Purpose:  change a replica location in replica set
  Format:   update_location (in saga:url name_old,
                           in saga:url name_new);
  Inputs:   name_old       replica to be updated
            name_new       update of replica
!
+ InOuts:   -
+ Outputs:  -
+ PreCond:  -
+ PostCond: - name_old is not anymore in list of replica
              locations for the logical file.
+           - name_new is in the list of replica locations
+             for the logical file.
+ Perms:    Read
+           Write
+ Throws:   NotImplemented
            IncorrectURL
            BadParameter
            AlreadyExists
            DoesNotExist
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
  Notes:    - this method removes a given replica location
              from the set of locations associated with the
              logical file, and adds a new location.
            - the implementation MAY choose to interpret the
              replica locations associated with the logical
!           file. It MAY return an 'IncorrectURL' error
              indicating an invalid location if it is unable

```

```

!           or unwilling to handle that specific locations
!           scheme. The implementation documentation MUST
!           specify how valid replica locations are formed.
!           - if 'name' can be parsed as URL, but contains
!           an invalid entry name, a 'BadParameter'
!           exception is thrown.
!           - if the old replica location is not in the
!           set of locations, a 'DoesNotExist' exception
!           is thrown.
-           and the new replica location is not added.
+           - if the new replica location is already in the
+           set of locations, an 'AlreadyExists' exception
+           is thrown.
+           - if the logical file was opened ReadOnly, an
+           'PermissionDenied' exception is thrown.
+           - if the logical file was opened WriteOnly, an
+           'PermissionDenied' exception is thrown.

- list_locations
  Purpose: list the locations in the location set
  Format: list_locations (out array<saga:url> names);
  Inputs: -
+  InOuts: -
  Outputs: names:          array of locations in set
+  PreCond: -
+  PostCond: -
+  Perms: Read
  Throws: NotImplemented
          IncorrectState
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          Timeout
          NoSuccess
  Notes: - this method returns an array of urls
          containing the complete set of locations
          associated with the logical file.
          - an empty array returned is not an error -
            the logical file object is still a valid
            object (see replicate() method description).
+          - if the logical file was opened WriteOnly, an
+          'PermissionDenied' exception is thrown.

- replicate

```

```

Purpose: replicate a file from any of the known
         replica locations to a new location, and, on
         success, add the new replica location to the
         set of associated replicas
Format:  replicate      (in  saga::url name,
                        in  int      flags = None);
Inputs:  name:          location to replicate to
         flags:         flags defining the operation
                        modus
+   InOuts:  -
+   Outputs: -
+   PreCond: -
+   PostCond: - an identical copy of one of the available
+               replicas exists at name.
+               - name is in the list of replica locations
+               for the logical file.
+   Perms:   Read
+           Write
+   Throws:  NotImplemented
           IncorrectURL
           BadParameter
           AlreadyExists
           DoesNotExist
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
Notes:     - the method implies a two step operation:
!           1) create a new and complete replica at the
!             given location, which then represents
             a new replica location.
           2) perform an add_location() for the new
             replica location.
           - all notes to the saga::ns_entry::copy() and
             saga::local_file::add_location methods
             apply.
           - the method is not required to be atomic, but:
             the implementation MUST be either
             successful in both steps, or throw an
             exception indicating if both methods failed,
             or if one of the methods succeeded.
           - a replicate call on an instance with empty
!           location set raises an 'IncorrectState'
             exception, with an descriptive error message.

```

```

!           - the default flags are 'None' (0). The
              interpretation of flags is as described for
              the ns_entry::copy() method.
+           - The 'Recursive' flag is not allowed, and
+             causes a 'BadParameter' exception.
+           - if the logical file was opened ReadOnly, an
+             'PermissionDenied' exception is thrown.
+           - if the logical file was opened WriteOnly, an
+             'PermissionDenied' exception is thrown.

```

Class logical_directory

This class represents a container for logical files in a logical file name space. It allows traversal of the catalog's name space, and the manipulation and creation (open) of logical files in that name space.

Constructor / Destructor:

```

- CONSTRUCTOR
  Purpose:  create the object
!   Format:  CONSTRUCTOR      (in session      s,
                              in saga::url    name,
                              in int         flags = Read,
                              out logical_directory
                              obj)
!   Inputs:  s:               session to associate with
                              the object
              name:           location of directory
              flags:          mode for opening
+   InOuts:  -
+   Outputs: obj:             the newly created object
+   PreCond: -
+   PostCond: - the logical_directory is opened.
+              - 'Owner' of target is the id of the context
+                use to perform the operation, if the
+                logical_directory gets created.
+   Perms:   Exec for parent directory.
+            Write for parent directory if Create is set.
+            Write for name if Write is set.
+            Read  for name if Read  is set.

```

```

        Throws:  NotImplemented
                  IncorrectURL
                  BadParameter
+               AlreadyExists
                  DoesNotExist
                  PermissionDenied
                  AuthorizationFailed
!               AuthenticationFailed
                  Timeout
                  NoSuccess
        Notes:   - the semantics of the inherited constructors
                  and of the logical_directory::open_dir()
                  method apply.
!               - the default flags are 'Read' (512).

- DESTRUCTOR
  Purpose:  destroy the object
  Format:   DESTRUCTOR          (in  logical_directory obj)
  Inputs:   obj:                the object to destroy
+  InOuts:   -
  Outputs:   -
+  PreCond:   -
+  PostCond: - the logical_directory is closed.
+  Perms:     -
+  Throws:    -
  Notes:     - the semantics of the inherited destructors
              apply.

- is_file
  Alias:     for is_entry of saga::ns_directory

- open_dir
  Purpose:   creates a new logical_directory instance
  Format:    open_dir          (in  saga::url name,
                              in  int      flags = Read,
                              out logical_directory dir);
  Inputs:    name:             name of directory to open
!            flags:            flags defining operation
                              modus
+  InOuts:    -
  Outputs:    dir:              opened directory instance
+  PreCond:    -
+  PostCond: - the session of the returned instance is that of

```

```

+         the calling instance.
+         - 'Owner' of name is the id of the context
+           used to perform the operation if name gets
+           created.
+   Perms:   Exec   for name's parent directory.
+           Write for name's parent directory if Create is set.
+           Write for name if Write is set.
+           Read  for name if Read  is set.
+   Throws:  NotImplemented
+           IncorrectURL
+           BadParameter
+           AlreadyExists
+           DoesNotExist
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes:   - all notes from the ns_directory::open_dir()
+             method apply.
!           - default flags are 'Read' (512).

- open
  Purpose:  creates a new logical_file instance
  Format:   open          (in saga::url  name,
                        in int      flags = Read,
                        out logical_file file);
  Inputs:   name:         file to be opened
!           flags:        flags defining operation
                        modus
+   InOuts:  -
+   Outputs: file:         opened file instance
+   PreCond: -
+   PostCond: - the session of the returned instance is that of
+               the calling instance.
+               - 'Owner' of name is the id of the context
+                 used to perform the operation if name gets
+                 created.
+   Perms:   Exec   for name's parent directory.
+           Write for name's parent directory if Create is set.
+           Write for name if Write is set.
+           Read  for name if Read  is set.
+   Throws:  NotImplemented
+           IncorrectURL

```

```

        BadParameter
        AlreadyExists
        DoesNotExist
        IncorrectState
        PermissionDenied
        AuthorizationFailed
        AuthenticationFailed
        Timeout
        NoSuccess
    Notes:  - all notes from the ns_directory::open() method
            apply.
            - the flag set 'Read | Write' is equivalent to
              the flag 'ReadWrite'.
    !
    - default flags are 'Read' (512).

- find
    Purpose: find entries in the current directory and below,
             with matching names and matching meta data
    Format:  find      (in  string      name_pattern,
    !                      in  array<string>  attr_pattern,
    -                      in  array<string>  val_pattern,
    -                      in  int           flags = None,
    +                      in  int           flags = Recursive,
                      out array<saga::url> names);
    Inputs:  name_pattern: pattern for names of
                      entries to be found
    !          attr_pattern: pattern for meta data
    !                      key/values of entries to be
                      found
    -          val_pattern: pattern for meta data values
    -                      of entries to be found
                      flags: flags defining the operation
                      modus
    +    InOuts:  -
    Outputs:  names:      array of names matching both
                      pattern
    +    PreCond:  -
    +    PostCond: -
    +    Perms:   Read   for cwd.
                Query for entries specified by name_pattern.
    +            Exec   for parent directories of these entries.
    +            Query for parent directories of these entries.
    +            Read   for directories specified by name_pattern.
    +            Exec   for directories specified by name_pattern.
    +            Exec   for parent directories of these directories.

```

```

+           Query for parent directories of these directories.
    Throws:  NotImplemented
            BadParameter
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
!    Notes:  - the description of find() in the Introduction
              to this section applies.
              - the semantics for both the find_attributes()
                method in the saga::attributes interface and
                for the find() method in the
                saga::ns_directory class apply. On
!            conflicts, the find() semantic supersedes
!            the find_attributes() semantic. Only entries
!            matching all attribute patterns and the name
!            space pattern are returned.
-           - the default flag set is 'None' (2).
+           - the default flags are 'Recursive' (2).

```

4.4.4 Examples

Code Example

```

1  // c++ example
2  int main ()
3  {
4      saga::logical_file lf ("lfn://remote.catalog.net/tmp/file1");
5
6      lf.replicate ("gsiftp://localhost/tmp/file.rep");
7      saga::file f ("gsiftp://localhost/tmp/file.rep");
8
9      std::cout << "size of local replica: "
10                 << f.get_size ()
11                 << std::endl;
12
13     return (0);
14 }

```

4.5 SAGA Streams

A number of use cases involve launching *of* remotely located components in order to create distributed applications. These use cases require simple remote socket connections to be established between these components and their control interfaces.

The target of the streams API is to establish the simplest possible authenticated socket connection with hooks to support *application level authorization and encryption schemes*. The stream API *has the following characteristics*

1. *It* is not performance oriented: If performance is required, then it is better to program directly against the APIs of existing performance oriented protocols like GridFTP or XIO. The API design should allow, however, for *high* performance implementations.
2. *It* is focused on TCP/IP socket connections. There has been no attempt to generalize this to arbitrary streaming interfaces (although it does not prevent such things as connectionless *protocols* from being supported).
3. *It* does not attempt to create a programming paradigm that diverges very far from baseline BSD sockets, Winsock, or Java Sockets.

This API greatly reduces the complexity of establishing authenticated socket connections in order to communicate with remotely located components. It however, provides very limited functionality and is thus suitable for applications that do not have very sophisticated requirements (as per 80-20 rule). It is envisaged that as applications become progressively more sophisticated, they will *gradually move* to more *the* sophisticated, native APIs in order to support those needs.

Several SAGA use cases require a more abstract communication API, which exchanges opaque messages instead of byte streams. That behaviour can be modelled on top of this stream API, but future versions of the SAGA API may introduce higher level communication APIs.

4.5.1 Endpoint URLs

The SAGA stream API uses URLs to specify connection endpoints. These URLs are supposed to allow SAGA implementations to be interoperable. For example, the URL

```
tcp://remote.host.net:1234/
```

is supposed to signal that a standard `tcp` connection can be established with host `remote.host.net` on port 1234. No matter what the specified URL scheme is, the SAGA stream API implementation **MUST** have the same semantics on API level, i.e. behave like a reliable byte-oriented data stream.

4.5.2 Endpoint Permissions

The SAGA API allows for application level authorization of stream communications: an application is able to set permissions on `saga::stream_server` and `saga::stream` instances. These permissions control what remote party can perform what action on those streams, e.g. control what remote parties are able to connect to an endpoint, or to write to them etc.

*Not all implementations will be able to fully implement that security model – the implementation **MUST** carefully document which permissions are supported, and which are not.*

4.5.3 Specification

```
package saga.stream
{
    enum state
    {
        New           = 1
        Open          = 2,
        Closed        = 3,
        Dropped       = 4,
        Error         = 5
    }

    enum activity
    {
        Read          = 1,
        Write         = 2,
        Exception     = 4
    }

    class stream_service : implements saga::object
                          implements saga::async
                          implements saga::monitorable
+                          implements saga::permissions
```

```

// from object saga::error_handler
{
!   CONSTRUCTOR      (in   session      s,
!                     in   saga::url     url,
                        out   stream_service obj);
!   DESTRUCTOR       (in   stream_service obj);

!   get_url          (out   saga::url     url);

!   serve             (in   float        timeout = -1.0,
                        out   stream      stream);

!   close            (in   float        timeout = 0.0);

!   // Metrics:

```

4.5.4 Specification Details

Enum state

A SAGA stream can be in several states – the complete state diagram is shown in Figure 6. The stream states are:

New

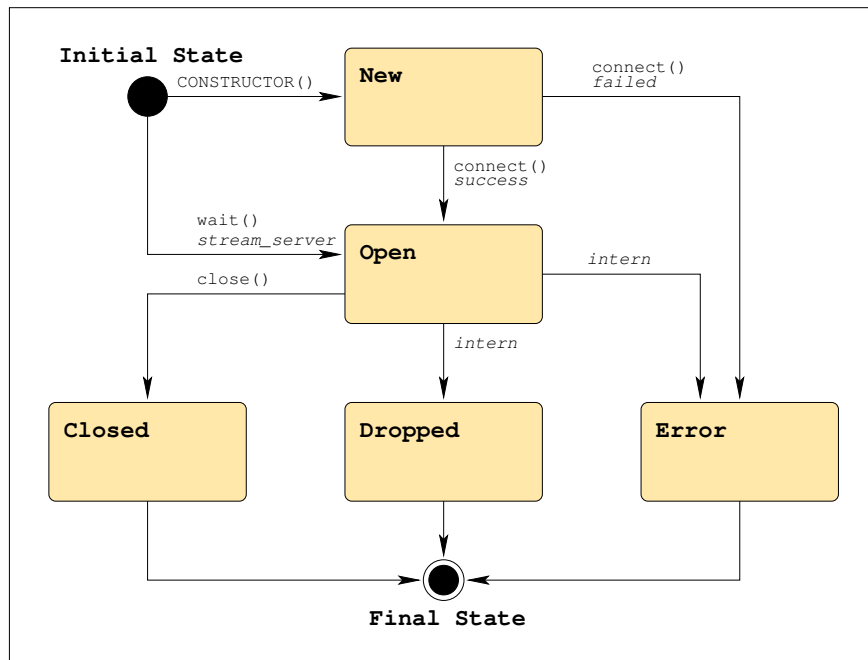

Figure 6: The SAGA stream state model (See Figure 1 for a legend).

A newly constructed stream enters the initial **New** state. It is not connected yet, and no I/O operations can be performed on it. `connect()` must be called to advance the state to **Open** (on success) or **Error** (on failure).

Open

The stream is connected to the remote endpoint, and I/O operations can be called. If any error occurs on the stream, it will move into the **Error** state. If the remote party closes the connection, the stream will move into the **Dropped** state. If `close()` is called on the stream, the stream will enter the **Closed** state.

Closed

The `close()` method was called on the stream – I/O is no longer possible. This is a final state.

Dropped

The remote party closed the connection – I/O is no longer possible. This is a final state.

Error

An error occurred on the stream – I/O is no longer possible. This is a final state. The exact reason for reaching this state **MUST** be available through the `error_handler` interface.

All method calls, apart from the `DESTRUCTOR`, will cause an `IncorrectState` exception if the stream is in a final state.

Enum activity_type

The SAGA stream API allows for event driven communication. A stream can flag activities, i.e. `Read`, `Write` and `Exception`, and the application can react on these activities. It is possible to poll for these events (using `wait()` with a potential timeout), or to get asynchronous notification of these events, by using the `respective` metrics.

Read

Data are available on the stream, and a subsequent `read()` will succeed.

Write

The stream is accepting data, and a subsequent `write()` will succeed.

Exception

An error occurred on the stream, and a following I/O operation may fail.

Class stream_service

The `stream_service` object establishes a listening/server object that waits for client connections. It can *only* be used as a factory for `client` sockets. It doesn't do any read/write I/O.

```

- CONSTRUCTOR
  Purpose:  create a new stream_service object
!   Format:  CONSTRUCTOR      (in session s,
!                               in saga::url url = "",
!                               out stream_service obj);
!   Inputs:  s:                session to be used for
                                object creation
                                url:      channel name or url,
                                           defines the source side
                                           binding for the stream

```

```

+   InOuts:  -
+   Outputs: obj:          new stream_service object
+   PreCond:  -
+   PostCond: - stream_service can wait for incoming
+               connections.
+               - 'Owner' of name is the id of the context
+               used to create the stream_service.
+               - the stream_server has 'Exec', 'Query', 'Read'
+               and 'Write' permissions for '*'.
+   Perms:    -
+   Throws:   NotImplemented
+               IncorrectURL
+               BadParameter
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
-   Notes:    - if the resource information given in the URL
-               cannot ever be used by the implementation
-               (e.g. the hostname is not well formatted,
-               or the scheme is not available), an
-               'IncorrectURL' exception is thrown, which
-               must contain a detailed error message.
+   Notes:    - if the given url is an empty string (the
+               default), the implementation will choose an
+               appropriate default value.
+               - the implementation MUST ensure that the given
+               URL is usable, and a later call to 'serve'
+               will not fail because of the information given
+               by the URL - otherwise, a 'BadParameter'
+               exception MUST be thrown.

- DESTRUCTOR
  Purpose:   Destructor for stream_service object.
  Format:    DESTRUCTOR          (in stream_service obj)
!   Inputs:  obj:                object to be destroyed
+   InOuts:  -
+   Outputs: -
+   PreCond: -
!   PostCond: - the stream_service is closed.
+   Perms:   -
+   Throws:  -
+   Notes:   - if the instance was not closed before, the
!               destructor performs a close() on the instance,

```

and all notes to close() apply.

```
// inspection
- get_url
  Purpose: get URL to be used to connect to this server
!   Format: get_url          (out saga:url url);
    Inputs: -
+   InOuts: -
    Outputs: url:           the URL of the connection.
+   PreCond: -
+   PostCond: -
+   Perms: -
    Throws: NotImplemented
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
-   Throws: -
    Notes: - returns a URL which can be passed to
!           the stream constructor to create a connection
           to this stream_service.

// stream management
- serve
  Purpose: wait for incoming client connections
  Format:  serve          (in float  timeout,
                          out stream client);
    Inputs: timeout:      number of seconds to wait
!           for a client
+   InOuts: -
    Outputs: client:      new Connected stream object
+   PreCond: -
    PostCond: - the returned client is in 'Open' state.
               - the session of the returned client is that of
                 the stream_server.
+   Perms: - Exec.
+           - Exec for the connecting remote party.
    Throws: NotImplemented
-           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
```

```

+           NoSuccess
+           Timeout
+           Notes: - if successful, it returns a new stream object
+                   that is connected to the client.
-                   - returns NULL or equivalent if it times out.
+                   - if no client connects within the specified
+                   timeout, a 'Timeout' exception is thrown.
-                   - if connection setup failed (not on timeout!),
+                   the returned client is in the 'Error' state.
+                   Its error_handler interface should give
+                   detailed information about the reason.
-                   - if the resource information given in the URL
-                   (during construction) cannot be used
-                   temporarily (e.g. the port is already taken),
-                   a 'BadParameter' exception is thrown, which
-                   must contain a detailed error message.
-                   - in the asynchronous case, the resulting client
-                   stream is passed by reference. That reference
-                   must be in the 'New' state - otherwise an
-                   'IncorrectState' exception is thrown.
!                   - for timeout semantics, see Section 2.

- close
!   Purpose: closes a stream service
+   Format: close (in float timeout)
+   Inputs: timeout seconds to wait
+   InOuts: -
+   Outputs: -
!   PreCond: -
!   PostCond: - no clients are accepted anymore.
+               - no callbacks registered for the
+               'ClientConnect' metric are invoked.
+   Perms: -
+   Throws: NotImplemented
+           IncorrectState
+           NoSuccess
-   Notes: - if a stream_service was closed earlier
-           an 'IncorrectState' exception is thrown.
+   Notes: - any subsequent method call on the object
+           MUST raise an 'IncorrectState' exception
+           (apart from DESTRUCTOR and close()).
+           - if close() is implicitly called in the
+           DESTRUCTOR, it will never throw an exception.
+           - close() can be called multiple times, with no
+           side effects.

```

-
- it is assumed that a session which opened the
 - instance can also close it - otherwise the
 - backend entity must have changed its state,
 - which causes an 'IncorrectState' exception.
 - for resource deallocation semantics, see
 - ! Section 2.
 - ! - for timeout semantics, see Section 2.
-

Class stream

This is the object that encapsulates all client stream objects.

Constructor / Destructor:

- CONSTRUCTOR
- ! Purpose: Constructor, initializes a client stream,
- ! for later connection to a server.
- ! Format: CONSTRUCTOR (in session s,
- ! in saga::url url,
- ! out stream obj);
- ! Inputs: s: saga session handle
- ! url: server location as URL
- + InOuts: -
- ! Outputs: obj: new, unconnected stream
- ! instance
- + PreCond: -
- PostCond: - the state of the socket is 'New'.
- + Perms: - Query for the stream_service represented by
- + url.
- Throws: NotImplemented
- IncorrectURL
- + BadParameter
- PermissionDenied
- AuthorizationFailed
- AuthenticationFailed
- Timeout
- NoSuccess
- ! Notes: - server location and possibly protocol are
- described by the input URL - see description
- above.

```

-         - if the resource information given in the URL
-           cannot ever be used by the implementation
-           (e.g. the hostname is not well formatted,
-           or the scheme is not available), an
-           'IncorrectURL' exception is thrown, which
-           must contain a detailed error message.
-         - the 'url' can be empty (which is the default).
!         A stream so constructed is only to be used
          as parameter to an asynchronous
          stream_server::serve() call. For such a
          stream, a later call to connect() will fail.
+         - the implementation MUST ensure that the
+           information given in the URL are usable -
+           otherwise a 'BadParameter' exception MUST be
+           thrown.
+         - the socket is only connected after the
+           connect() method is called.

- DESTRUCTOR
!   Purpose:  destroy a stream object
          Format:  DESTRUCTOR          (in stream obj)
          Inputs:  obj:                stream to destroy
+   InOuts:    -
          Outputs: -
+   PreCond:    -
+   PostCond:   - the socket is closed.
+   Perms:      -
          Throws: -
+   Notes:      - if the instance was not closed before, the
+                 destructor performs a close() on the instance,
+                 and all notes to close() apply.

```

Inspection methods:

```

- get_url
!   Purpose:  get URL used for creating the stream
!   Format:   get_url                  (out saga::url url);
          Inputs:  -
+   InOuts:    -
!   Outputs:   url:                    the URL of the connection.
+   PreCond:    -
+   PostCond:   -
+   Perms:      -

```

```

        Throws:    NotImplemented
                  IncorrectState
                  PermissionDenied
                  AuthorizationFailed
                  AuthenticationFailed
                  Timeout
                  NoSuccess
-   Throws:      -
    Notes:      - returns a URL which can be passed to a
                  stream constructor to create another
                  connection to the same stream_service.
                  - the returned url may be empty, indicating that
                    this instance has been created with an empty
                    url as parameter to the stream CONSTRUCTOR().

-   get_context
    Purpose:    return remote authorization info
    Format:     get_context          (out context ctx);
    Inputs:     -
+   InOuts:    -
    Outputs:    ctx:                remote context
    PreCond:    - the stream is, or has been, in the 'Open'
                  state.
!   PostCond:  - the returned context is deep copied, and does
                  not share state with any other object.
+   Perms:     -
    Throws:    NotImplemented
                  IncorrectState
                  PermissionDenied
                  AuthorizationFailed
                  AuthenticationFailed
                  Timeout
                  NoSuccess
-   Throws:    -
    Notes:      - the context returned contains the security
                  information from the REMOTE party, and can be
                  used for authorization.
                  - if the stream is in a final state, but has
                    been in 'Open' state before, the returned
                    context represents the remote party the stream
!   has been connected to while it was in 'Open'
                    state.
                  - if the stream is not in 'Open' state, and is
                    not in a final state after having been in
                    'Open' state, an 'IncorrectState' exception is

```

```

        thrown.
        - if no security information are available, the
          returned context has the type 'Unknown' and no
!       attributes are attached.
        - the returned context MUST be authenticated, or
          must be of type 'Unknown' as described above.

```

Management methods:

```

-----

- connect
  Purpose: Establishes a connection to the target defined
           during the construction of the stream.
  Format:  connect                (void);
  Inputs:  -
+  InOuts: -
  Outputs: -
  PreCond: - the stream is in 'New' state.
  PostCond: - the stream is in 'Open' state.
+  Perms:   Exec for the stream_service represented by the
+           url used for creating this stream instance.
  Throws:   NotImplemented
-           BadParameter
           IncorrectState
           PermissionDenied
           AuthorizationFailed
           AuthenticationFailed
           Timeout
           NoSuccess
  Notes:    - on failure, the stream state is changed to
!           'Error'
           - if the stream instance is not in 'New' state,
-           an 'IncorrectState' exception is thrown.
           - if the resource information given in the URL
-           (during construction) cannot be used
-           temporarily (e.g. the port is already taken),
-           a 'BadParameter' exception is thrown, which
-           must contain a detailed error message.

- close
  Purpose: closes an active connection
  Format:  close                (in float timeout)
  Inputs:  timeout              seconds to wait
+  InOuts: -

```

```

        Outputs: -
!       PreCond: -
        PostCond: - stream is in 'Closed' state
+       Perms: -
        Throws:  NotImplemented
                IncorrectState
                NoSuccess
-       Throws:  IncorrectState
-       Notes:   - if a stream was closed earlier (i.e. it is
-                 in 'Closed' or 'Dropped' state), this method
-                 does nothing, and, in particular, does not
-                 throw an 'IncorrectState' exception.
+       Notes:   - any subsequent method call on the object
+                 MUST raise an 'IncorrectState' exception
+                 (apart from DESTRUCTOR and close()).
+                 - if close() is implicitly called in the
+                 DESTRUCTOR, it will never throw an exception.
+                 - close() can be called multiple times, with no
+                 side effects.
-                 - it is assumed that a session which opened the
-                 instance can also close it - otherwise the
-                 backend entity must have changed its state,
-                 which causes an 'IncorrectState' exception.
-                 - for resource deallocation semantics, see
!                 Section 2.
!                 - for timeout semantics, see Section 2.

```

Stream I/O methods:

```

- read
!   Purpose: Read a data buffer from stream.
-   Format:  read          (inout array<byte> buffer,
+   Format:  read          (inout buffer      buf,
!                                     in   int          len_in = -1,
!                                     out  int          len_out);
        Inputs:  len_in:    Maximum number of bytes
!                                     that can be copied into
!                                     the buffer.
!   InOuts:   buf:         buffer to store read data
!                                     into
        Outputs:  len_out:  number of bytes read, if
!                                     successful.
+   PreCond:  - the stream is in 'Open' state.
+   PostCond: - data from the stream are available in the

```

```

+         buffer.
+   Perms:   Read for the stream_service represented by the
+           url used for creating this stream instance.
+   Throws:  NotImplemented
+           BadParameter
-           WriteOnly
+           IncorrectState
+           PermissionDenied
+           AuthorizationFailed
+           AuthenticationFailed
+           Timeout
+           NoSuccess
+   Notes:   - if the stream is blocking, the call waits
+             until data become available.
+             - if the stream is non-blocking, the call
+               returns immediately, even if no data are
+               available -- that is not an error condition.
!             - the actually number of bytes read into buffer
!               is returned in len_out. It is not an error
!               to read less bytes than requested, or in fact
!               zero bytes.
!             - errors are indicated by returning negative
!               values for len_out, which correspond to
!               negatives of the respective ERRNO error code
!             - the given buffer must be large enough to
!               store up to len_in bytes, or managed by the
!               implementation - otherwise a 'BadParameter'
!               exception is thrown.
+             - the notes about memory management from the
+               buffer class apply.
!             - if len_in is smaller than 0, or not given,
!               the buffer size is used for len_in.
!               If that is also not available, a
!               'BadParameter' exception is thrown.
!             - if the stream is not in 'Open' state, an
!               'IncorrectState' exception is thrown.
!             - similar to read (2) as specified by POSIX

- write
!   Purpose: Write a data buffer to stream.
-   Format:  write          (in array<byte>  buffer,
+   Format:  write          (in buffer        buf,
!           in int          len_in = -1,
!           out int         len_out);
+   Inputs:  len_in:        number of bytes of data in

```

```

!           buffer:           the buffer
                                buffer containing data
                                that will be sent out via
                                socket
+   InOuts:  -
Outputs: len_out:           bytes written if successful
PreCond:  - the stream is in 'Open' state.
+   PostCond: - the buffer data are written to the stream.
+   Perms:   Write for the stream_service represented by the
+           url used for creating this stream instance.
+   Throws:  NotImplemented
            BadParameter
-           ReadOnly
            IncorrectState
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
Notes:  - if the stream is blocking, the call waits
        until the data can be written.
        - if the stream is non-blocking, the call
        returns immediately, even if no data are
        written -- that is not an error condition.
!       - it is not an error to write less than len_in
!       bytes.
!       - errors are indicated by returning negative
!       values for len_out, which correspond to
!       negatives of the respective ERRNO error code
!       - the given buffer must be large enough to
!       store up to len_in bytes, or managed by the
!       implementation - otherwise a 'BadParameter'
!       exception is thrown.
+       - the notes about memory management from the
+       buffer class apply.
!       - if len_in is smaller than 0, or not given,
!       the buffer size is used for len_in.
!       If that is also not available, a
!       'BadParameter' exception is thrown.
!       - if the stream is not in 'Open' state, an
!       'IncorrectState' exception is thrown.
!       - similar to write (2) as specified by POSIX

- wait
Purpose: check if stream is ready for reading/writing, or

```

```

        if it has entered an error state.
Format:  wait                               (in int    what,
                                           in float  timeout,
                                           out int    cause);
Inputs:  what:                             activity types to wait for
        timeout:                          number of seconds to wait
+ InOuts: -
Outputs: cause:                             activity type causing the
                                           call to return
PreCond: - the stream is in 'Open' state.
+ PostCond: - the stream can be read from, or written to, or
+           it is in 'Error' state.
+ Perms:   -
Throws:    NotImplemented
          IncorrectState
          PermissionDenied
          AuthorizationFailed
          AuthenticationFailed
          NoSuccess
- Throws:  IncorrectState
Notes:    - wait will only check on the conditions
          specified by 'what'
          - 'what' is an integer representing
            OR'ed 'Read', 'Write', or 'Exception' flags.
!         - 'cause' describes the availability of the
          socket (eg. OR'ed 'Read', 'Write', or
          'Exception')
!         - for timeout semantics, see Section 2.
!         - if the stream is not in 'Open' state, an
          'IncorrectState' exception is thrown.

```

4.5.5 Examples

Code Example

```

1  Sample SSL/Secure Client:
2  -----
3
4  Opens a stream connection using native security: the
5  context is passed in implicitly via the default SAGA
6  session's contexts.
7  (GSI or SSL security)
8
9  // C++/JAVA Style
10  ssize_t recvlen;

```

```

11     saga::buffer b;
12     saga::stream s ("localhost:5000");
13
14     s.connect ();
15     s.write  (saga::buffer ("Hello World!"));
16
17     // blocking read, read up to 128 bytes
18     recvlen = s.read (b, 128);
19
20
21     /* C Style */
22     ssize_t recvlen;
23
24     SAGA_stream sock = SAGA_Stream_open ("localhost:5000");
25     SAGA_buffer b_in = SAGA_Buffer_create ("Hello World");
26     SAGA_buffer b_out = SAGA_Buffer_create ("Hello World");
27
28     SAGA_Stream_connect (sock);
29     SAGA_Stream_write  (sock, b_in);
30
31     /* blocking read, read up to 128 bytes */
32     recvlen = SAGA_Stream_read (sock, b_out, 128);
33
34
35     c Fortran Style */
36     INTEGER  err,SAGAStrRead,SAGAStrWrite,err
37     INTEGER*8 SAGAStrOpen,streamhandle
38     CHARACTER buffer(128)
39     SAGAStrOpen("localhost:5000",streamhandle)
40     call SAGAStrConnect(streamhandle)
41     err = SAGAStrWrite(streamhandle,"localhost:5000",12)
42     err = SAGAStrRead(streamhandle,buffer,128)
43
44
45     Sample Secure Server:
46     -----
47
48     Once a connection is made, the server can use information
49     about the authenticated client to make an authorization
50     decision
51
52     // c++ example
53     saga::stream_service server ("tcp://localhost/5000");
54
55     saga::stream client;
56
57     // now wait for a connection
58     while ( saga::stream::Open != client.get_state () )
59     {
60         // wait forever for connection

```

```
61         client = server.serve ();
62
63         // get remote security details
64         saga::context ctx = client.get_context ();
65
66         // check if context type is X509, and if DN is the
67         // authorized one
68         if ( ctx.type () == "X509" &&
69             ctx.get_attribute ("DN") == some_auth_dn )
70         {
71             // allowed - keep open and leave loop
72             client.write (saga::buffer ("Hello!"));
73         }
74         else
75         {
76             client.close (); // not allowed
77         }
78     }
79
80     // start activity on client socket...
```

Example for async stream server

```
84     -----
85
86     // c++ example
87     class my_cb : public saga::callback
88     {
89     private:
90         saga::stream_service ss;
91         saga::stream s;
92
93     public:
94
95         my_cb (saga::stream_service ss_,
96               saga::stream s_)
97         {
98             ss = ss_;
99             s = s_;
100         }
101
102         bool cb (saga::monitorable mt,
103                 saga::metric m,
104                 saga::context c)
105         {
106             s = ss.serve ();
107             return (false); // want to be called only once
108         }
109     }
110
```

```
111     int main ()
112     {
113         saga::stream_service ss;
114         saga::stream          s;
115         my_cb cb (ss, s);
116
117         ss.add_callback ("client_connect", cb);
118
119         while ( true )
120         {
121             if ( s.state != saga::stream::Open )
122             {
123                 // no client, yet
124                 sleep (1);
125             }
126             else
127             {
128                 // handle open socket
129                 s.write ("Hello Client\r\n", 14);
130                 s.close ();
131
132                 // restart listening
133                 ss.add_callback ("client_connect", cb);
134             }
135         }
136
137         return (-1); // unreachable
138     }
```

4.6 SAGA Remote Procedure Call

GridRPC is one of the few high level APIs that have been specified by the GGF [19]. Thus including the GridRPC specification in the SAGA API benefits both SAGA and the GridRPC effort: SAGA becomes more complete and provides a better coverage of its use cases with a single **Look-&-Feel**, whilst GridRPC gets embedded into a set of other tools of similar scope, which opens it to a potentially wider user community, and ensures its further development.

Semantically, the methods defined in the GridRPC specification, as described in GFD.52 [19], map exactly with the RPC package of the SAGA API as described here. In essence, the GridRPC API has been imported into the SAGA RPC package, and has been equipped with the **Look-&-Feel**, error conventions, task model, etc. of the SAGA API.

The `rpc` class constructor initialises the remote function handle. This process may involve connection setup, service discovery, etc. The `rpc` class further offers one method `'call'`, which invokes the remote procedure, and returns the respective return data and values. The asynchronous call versions described in the GridRPC specification are realised by the SAGA task model, and are not represented as separate calls here.

In the constructor, the remote procedure to be invoked is specified by a URL, with the syntax:

```
gridrpc://server.net:1234/my_function
```

with the elements responding to:

<code>gridrpc</code>	–	scheme	–	identifying a grid rpc operation
<code>server.net</code>	–	server	–	server host serving the rpc call
<code>1234</code>	–	port	–	contact point for the server
<code>my_function</code>	–	name	–	name of the remote method to invoke

All elements can be empty, which allows the implementation to fall back to a default remote method to invoke.

The argument and return value handling is very basic, and reflects the traditional scheme for remote procedure calls, that is, an array of structures acts as variable parameter vector. For each element of the vector, the `parameter` struct describes its data `buffer`, the `size` of that buffer, and its input/output `mode`.

The `mode` value has to be initialized for each `parameter`, and `size` and `buffer` values have to be initialized for each `In` and `InOut` struct. For `Out` parameters, `size` may have the value 0 in which case the `buffer` must be un-allocated, and

is to be created (e.g. allocated) by the SAGA implementation upon arrival of the result data, with a size sufficient to hold all result data. The `size` value is to be set by the implementation to the allocated buffer size. SAGA language bindings **MUST** prescribe the responsibilities for releasing the allocated buffer, according to usual procedures in the respective languages.

When an `Out` or `InOut` struct uses a pre-allocated buffer, any data exceeding the buffer size are discarded. The application is responsible for specifying correct buffer sizes for pre-allocated buffers; otherwise the behaviour is undefined.

This argument handling scheme allows efficient (copy-free) passing of parameters. The parameter vector must be passed by reference because it is specified as `inout` in SIDL. (See also Section 2.2.)

4.6.1 RPC Permissions

*The SAGA API allows for application level authorization of RPC calls an application is able to set permissions on `saga::rpc` instances. Not all implementations will be able to fully implement that security model – the implementation **MUST** carefully document which permissions are supported, and which are not.*

4.6.2 Specification

```

package saga.rpc
{
    enum io_mode
    {
        In    = 1,          // input  parameter
        Out   = 2,          // output parameter
        InOut = 3           // input and output parameter
    }

-   struct parameter
-   {
-       int          size;  // number of bytes in buffer
-       array<byte> buffer; // data
-       io_mode      mode;  // parameter mode
-   }
-
+   class parameter : extends saga::buffer
+       // from buffer saga::object
+       // from object saga::error_handler

```

```

+ {
+     CONSTRUCTOR (in    array<byte>    data = "",
+                  in    int             size = 0,
+                  in    io_mode         mode = In,
+                  out   buffer          obj);
+
+     set_io_mode (in    io_mode         mode);
+     get_io_mode (out   io_mode         mode);
+ }

class rpc : implements saga::object
           implements saga::async
+         implements saga::permissions
           // from object saga::error_handler
{
!     CONSTRUCTOR (in    session         s,
!                  in    saga::url       url = "",
!                  out   rpc             obj          );
!     DESTRUCTOR  (in    rpc             obj          );

    // rpc method invocation
    call          (inout array<parameter> parameters );

    // handle management
    close         (in    float           timeout = 0.0);
}
}

```

4.6.3 Specification Details

Enum io_mode

The io_mode enum specifies the modus of the `rpc::parameter` instances:

In

The parameter is an input parameter: its initial value will be evaluated, and its data buffer will not be changed during the invocation of `call()`.

Out

The parameter is an output parameter: its initial value will not be evaluated, and its data buffer will likely be changed during the invocation of `call()`.

InOut

The parameter is input and output parameter: its initial value will not be evaluated, and its data buffer will likely be changed during the invocation of `call()`.

Class parameter

The `parameter` class inherits the `saga::buffer` class, and adds one additional state attribute: `io_mode`, which is read-only. With that addition, the new class can conveniently be used to define input, inout and output parameters for RPC calls.

```

+   - CONSTRUCTOR
+   Purpose:  create an parameter instance
+   Format:   CONSTRUCTOR          (in  array<byte> data = "",
+                                   in  int           size = -1,
+                                   in  io_mode        mode = In,
+                                   out parameter      obj);
+   Inputs:   type:                 data to be used
+             size:                 size of data to be used
+             io_mode:              type of parameter
+   InOuts:   -
+   Outputs:  parameter:            the newly created parameter
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   NotImplemented
+             BadParameter
+             NoSuccess
+   Notes:    - all notes from the buffer CONSTRUCTOR apply.
+
+   - DESTRUCTOR
+   Purpose:  destroy an parameter instance
+   Format:   DESTRUCTOR          (in  parameter obj);
+   Inputs:   obj:                 the parameter to destroy
+   InOuts:   -
+   Outputs:  -
+   PreCond:  -
+   PostCond: -
+   Perms:    -
+   Throws:   -

```

```

+   Notes:    - all notes from the buffer DESTRUCTOR apply.
+
+
+   - set_io_mode
+     Purpose:  set io_mode
+     Format:   set_io_mode          (in io_mode mode);
+     Inputs:   mode:                value for io mode
+     InOuts:   -
+     Outputs:  -
+     PreCond:  -
+     PostCond: -
+     Perms:    -
+     Throws:   -
+     Notes:    -
+
+   - get_io_mode
+     Purpose:  retrieve the current value for io mode
+     Format:   get_io_mode          (out io_mode mode);
+     Inputs:   -
+     InOuts:   -
+     Outputs:  mode:                value of io mode
+     PreCond:  -
+     PostCond: -
+     Perms:    -
+     Throws:   -
+     Notes:    -

```

Class rpc

This class represents a remote function handle, which can be called (repeatedly), and returns the result of the respective remote procedure invocation.

```

-   Constructor / Destructor:
-   -----
-
-   - CONSTRUCTOR
-     ! Purpose:  initializes a remote function handle
-     ! Format:   CONSTRUCTOR (in session s,
-     !                               in saga::url url = "",
-     !                               out rpc      obj);
-     ! Inputs:   s:                saga session to use
-     !             funcname:        name of remote method to

```

```

                                initialize
    InOuts:  -
    Outputs: obj                the newly created object
+   PreCond: -
+   PostCond: - the instance is open.
+   Perms:   Query
    Throws:  NotImplemented
            IncorrectURL
            BadParameter
            DoesNotExist
            PermissionDenied
            AuthorizationFailed
            AuthenticationFailed
            Timeout
            NoSuccess
-   Notes:   - if the given 'url' cannot ever be used by
-             the implementation (e.g. the hostname is
-             not well formatted, or the scheme is not
-             available), an 'IncorrectURL' exception is
-             thrown, which must contain a detailed error
-             message.
!   Notes:   - if url is not given, or is empty (the
!             default), the implementation will choose an
              appropriate default value.
              - according to the GridRPC specification, the
                constructor may or may not contact the RPC
                server; absence of an exception does not imply
                that following RPC calls will succeed, or that
                a remote function handle is in fact available.
              - the following mapping MUST be applied from
                GridRPC errors to SAGA exceptions:
                GRPC_SERVER_NOT_FOUND    : BadParameter
                GRPC_FUNCTION_NOT_FOUND  : DoesNotExist
                GRPC_RPC_REFUSED         : AuthorizationFailed
                GRPC_OTHER_ERROR_CODE    : NoSuccess
              - non-GridRPC based implementations SHOULD ensure
!             upon object construction that the remote handle
              is available, for consistency with the
              semantics on other SAGA object constructors.

-   DESTRUCTOR
    Purpose: destroy the object
    Format:  DESTRUCTOR          (in rpc obj)
    Inputs:  obj:                the object to destroy
    InOuts:  -
    Outputs: -

```

```

+   PreCond:  -
+   PostCond: - the instance is closed.
+   Perms:    -
+   Throws:   -
+   Notes:    - if the instance was not closed before, the
!               destructor performs a close() on the instance,
                  and all notes to close() apply.

- call
  Purpose: call the remote procedure
  Format:  call      (inout array<parameter> param);
  Inputs:  -
  In/Out:  param:      argument/result values for call
  InOuts:  -
  Outputs: -
+   PreCond: - the instance is open.
+   PostCond: - the instance is available for another call()
+               invocation, even if the present call did not
+               yet finish, in the asynchronous case.
+   Perms:   Exec
+   Throws:  NotImplemented
+               IncorrectURL
+               BadParameter
+               DoesNotExist
+               IncorrectState
+               PermissionDenied
+               AuthorizationFailed
+               AuthenticationFailed
+               Timeout
+               NoSuccess
+   Notes:   - according to the GridRPC specification, the
!               RPC server might not be contacted before
                  invoking call(). For this reason, all notes to
                  the object constructor apply to the call()
                  method as well.
-               - if an implementation finds inconsistent
!               information in the parameter vector, a
                  'BadParameter' exception is thrown.
-               - arbitrary backend failures (e.g. semantic
!               failures in the provided parameter stack, or
                  any errors occurring during the execution of
                  the remote procedure) MUST be mapped to a
                  'NoSuccess' exception, with a descriptive
!               error message. That way, error semantics of
                  the SAGA implementation and of the RPC

```

```

        function implementation are strictly
        distinguished.
+       - the notes about memory management from the
+       buffer class apply.

- close
  Purpose: closes the rpc handle instance
  Format:  close          (in float timeout = 0.0);
  Inputs:  timeout        seconds to wait
  InOuts:  -
  Outputs: -
+  PreCond: -
+  PostCond: - the instance is closed.
+  Perms:   -
  Throws:  NotImplemented
           IncorrectState
           NoSuccess
-  Notes:   - an 'IncorrectState' exception is thrown if the
-           object was closed before.
+  Notes:   - any subsequent method call on the object
+           MUST raise an 'IncorrectState' exception
+           (apart from DESTRUCTOR and close()).
+           - if close() is implicitly called in the
+           DESTRUCTOR, it will never throw an exception.
+           - close() can be called multiple times, with no
+           side effects.
-           - it is assumed that a session which opened the
-           instance can also close it - otherwise the
-           backend entity must have changed its state,
-           which causes an 'IncorrectState' exception.
-           - for resource deallocation semantics, see
!           Section 2.
!           - for timeout semantics, see Section 2.

```

4.6.4 Examples

Code Example

```

1  // c++ example
2  // call a remote matrix multiplication A = A * B
3  try
4  {
5      rpc rpc ("gridrpc://rpc.matrix.net/matrix-mult");
6

```

```

7      std::vector <saga::rpc::parameter> params (2);
8
9      params[0].set_data (A); // ptr to matrix A
10     params[0].set_io_mode (saga::rpc::InOut);
11
12     params[1].set_data (B); // ptr to matrix B
13     params[1].set_io_mode (saga::rpc::In);
14
15     rpc.call (params);
16
17     // A now contains the result
18 }
19 catch ( const saga::exception & e)
20 {
21     std::err << "SAGA error: "
22              << e.get_message ()
23              << std::endl;
24 }
25
26 +-----+
27
28 // c++ example
29 // call a remote matrix multiplication C = A * B
30 try
31 {
32     rpc rpc ("gridrpc://rpc.matrix.net//matrix-mult-2");
33
34     std::vector <saga::rpc::parameter> params (3);
35
36     params[0].set_data (NULL); // buffer will be created
37     params[0].set_io_mode (saga::rpc::Out);
38
39     params[1].set_data (A); // ptr to matrix A
40     params[1].set_io_mode (saga::rpc::In);
41
42     params[2].set_data (B); // ptr to matrix B
43     params[2].set_io_mode (saga::rpc::In);
44
45     rpc.call (params);
46
47     // params[0].get_data () now contains the result
48 }
49 catch ( const saga::exception & e)
50 {
51     std::err << "SAGA error: "
52              << e.get_message ()
53              << std::endl;
54 }
55
56 +-----+

```

```
57
58 // c++ example
59 // asynchronous version of A = A * B
60 try
61 {
62     rpc rpc ("gridrpc://rpc.matrix.net/matrix-mult");
63
64     std::vector <saga::rpc::parameter> params (2);
65
66     params[0].set_data (A); // ptr to matrix A
67     params[0].set_io_mode (saga::rpc::InOut);
68
69     params[1].set_data (B); // ptr to matrix B
70     params[1].set_io_mode (saga::rpc::In);
71
72     saga::task t = rpc.call <saga::task::ASync> (params);
73
74     // do something else
75
76     t.wait ();
77     // A now contains the result
78 }
79 catch ( const saga::exception & e)

The initial version of the presented SAGA API was drafted by the SAGA Design Team. Members of that design team did not necessarily contribute text to the document, but did certainly contribute to its current state, and very much so. Additional to the authors listed above, the following people were members of the design team, in alphabetical order:

Hrabri Rajic (Intel), Keith Jackson (LBL), David Konerding (LBL), Gregor von Laszewski (ANL).

Further, the authors would like to thank all contributors from OGF's SAGA-RG and SAGA-CORE-WG, and other related groups. We would like to acknowledge, in alphabetical order, the contributions of:

Gabriele Allen (LSU), Stephan Hirmer (LSU), Craig Lee (Aerospace Corporation), Hidemoto Nakada (AIST), Steven Newhouse (OMII-UK), Stephen Pickles (University of Manchester), Ed Seidel (LSU), Derek Simmel (PSC), Yusuke Tanimura (AIST), Osamu Tatebe (University of Tsukuba).

5.2 Intellectual Property Statement

The OGF takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this specification can be obtained from the OGF Secretariat.

The OGF invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to practice this recommendation. Please address the information to the OGF Executive Director.

5.3 Disclaimer

This document and the information contained herein is provided on an "As Is" basis and the OGF disclaims all warranties, express or implied, including but not limited to any warranty that the use of the information herein will not infringe any rights or any implied warranties of merchantability or fitness for a particular purpose.

5.4 Full Copyright Notice

Copyright (C) Open Grid Forum (2006). All Rights Reserved.

This document and translations of it may be copied and furnished to others, and derivative works that comment on or otherwise explain it or assist in its implementation may be prepared, copied, published and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and this paragraph are included on all such copies and derivative works. However, this document itself may not be modified in any way, such as by removing the copyright notice or references to the OGF or other organizations, except as needed for the purpose of developing Grid Recommendations in which case the procedures for copyrights defined in the OGF Document process must be followed, or as required to translate it into languages other than English.

The limited permissions granted above are perpetual and will not be revoked by the OGF or its successors or assignees.

Appendix

A SAGA Code Examples

This appendix shows a couple of SAGA examples in different languages. As stated in the introduction, these examples are not normative – language bindings are outside the scope of this document. This appendix is rather supposed to illustrate how the authors imagine the use of the API in various languages.

We hope that the examples illustrate that the API stays SIMPLE in various language incarnations, as was the major design intent for the `_SAGA` API.

Code Example

```
1
2 Example 1 (C++): Object State:
3 =====
4
5 // This example illustrates the expected life
6 // times of object states. State is shared in
7 // these cases, as only shallow copies occur.
8
9 int main (void)
10 {
11     { // task scope
12         saga::task t;
13
14         { // file scope
15             saga::file f;
16
17             { // session scope
18                 saga::session s;
19
20                 { // context scope
21                     saga::context c (saga::context::UserPass);
22
23                     s.add_context (c);
24                     f (s, saga::url ("file:///tmp/data.bin"));
25                     t = f.copy <saga::task::Task>
26                         (saga::url ("file:///tmp/data.bak"));
27
28                 } // leave context scope
29                 // session keeps context state
30
31             } // leave session scope
32             // file keeps session state
33
34         } // file scope
```

```

35         // task keeps file state
36
37         t.run ();
38         // task runs, and uses state of file, session,
39         // and context.
40         t.wait ();
41
42     } // task scope
43     // task    releases file state
44     // file    releases session state
45     // session releases context state
46
47     return (0);
48 }
49
50
51 +-----+
52
53 Example 2: Files:
54 =====
55
56 open a file. if its size is > 10, then read the first 10
57 bytes into a string, print it, end return it.
58
59 -----
60 Example 2a: C++
61 -----
62 // c++ example
63 void head (const saga::url url)
64 {
65     try {
66         // get type and other infos
67         saga::file f (url);
68
69         off_t size = f.get_size ();
70
71         if ( size > 10 )
72         {
73             char    buf[11];
74
75             ssize_t len_out = f.read (saga::buffer (buf));
76
77             if ( 10 == len_out )
78             {
79                 std::cout << "head: "
80                         << buffer.get_data ()
81                         << std::endl;
82             }
83         }
84     }

```

```
85         catch ( const saga::exception & e )
86         {
87             std::cerr << "Oops! SAGA error: "
88                       << e.get_message ()
89                       << std::endl;
90         }
91     }
92
93     return;
94 }
95 -----
96 -----
97 Example 2b: C
98 -----
99     void head (const SAGA_URL url)
100    {
101        SAGA_File my_file = SAGA_File_create (url);
102
103        if ( NULL == my_file )
104        {
105            fprintf (stderr, "Could not create SAGA_File "
106                      "for %s: %s\n",
107                      SAGA_URL_get_url (url),
108                      SAGA_Session_get_error (theSession));
109            return (NULL);
110        }
111
112        off_t size = SAGA_File_get_size (my_file);
113
114        if ( size < 0 )
115        {
116            fprintf (stderr, "Could not determine file size "
117                      "for %s: %s\n",
118                      SAGA_URL_get_url (url),
119                      SAGA_Session_get_error (theSession));
120            return (NULL);
121        }
122        else if ( size >= 10 )
123        {
124            SAGA_buffer b = SAGA_Buffer_create ();
125            size_t buflen;
126
127            ssize_t ret = SAGA_File_read (my_file, b, 10);
128
129            if ( ret < 0 )
130            {
131                fprintf (stderr, "Could not read file %s: %s\n",
132                          SAGA_URL_get_url (url),
133                          SAGA_Session_get_error (theSession));
134            }
135        }
```

```
135         else if ( ret < 10 )
136         {
137             fprintf (stderr, "head: short read: %d\n", ret);
138         }
139         else
140         {
141             printf ("head: '%s'\n", SAGA_Buffer_get_data (b));
142         }
143     }
144     else
145     {
146         fprintf (stderr, "head: file %s is too short: %d\n",
147                 file, size);
148     }
149
150     return;
151 }
152
153 -----
154 Example 2c: Java
155 -----
156
157 import org.ogf.saga.URI;
158 import org.ogf.saga.buffer.Buffer;
159 import org.ogf.saga.buffer.BufferFactory;
160 import org.ogf.saga.file.File;
161 import org.ogf.saga.file.FileFactory;
162 import org.ogf.saga.namespace.Flags;
163 import org.ogf.saga.session.Session;
164
165 public class Example {
166     // open a file. if its size is >= 10, then read the first
167     // 10 bytes into a string, print it, end return it.
168     public String head(Session session, URI uri)
169     {
170         try
171         {
172             File f = FileFactory.createFile(session, uri, Flags.READ);
173             long size = f.getSize();
174
175             if (10 <= size) {
176                 Buffer    buffer = BufferFactory.createBuffer(10);
177                 int      res    = f.read(10, buffer);
178
179                 if (10 == res) {
180                     System.out.println("head: " + buffer);
181                 } else {
182                     System.err.println("head: read is short! " + res);
183                 }
184                 return new String(buffer.getData());
185             }
186         }
187     }
188 }
```

```

185         } else {
186             System.err.println("file is too small: " + size);
187         }
188     } catch (Exception e) {
189         // catch any possible error - see elsewhere for better
190         // examples of error handling in SAGA
191         System.err.println ("Oops! " + e);
192     }
193
194     return null;
195 }
196 }

```

Example 2d: Perl ('normal' error handling)

```

200
201 sub head ($)
202 {
203     my $url      = shift;
204     my $my_file = new saga::file ($url)
205         or die ("can't create file for $url: $!\n");
206
207     my $size      = my_file->get_size ();
208
209     if ( $size > 10 )
210     {
211         my $buffer = new saga::buffer (10)l
212         my $ret      = my_file->read ($buffer)
213             or die ("can't read from file $url: $!\n");
214
215         if ( $ret == 10 )
216         {
217             print "head: ", $buffer->get_data (), "\n";
218         }
219         else
220         {
221             printf STDERR "head: short read: %d\n" ($buffer);
222         }
223     }
224     else
225     {
226         print STDERR "file $url is too short: $size\n";
227     }
228
229     return;
230 }

```

Example 2e: Perl (exceptions)

```

235     sub head ($)
236     {
237         my $url      = shift;
238
239         eval
240         {
241             my $my_file = new saga::file ($url);
242             my $size     = my_file->get_size ();
243
244             if ( $size > 10 )
245             {
246                 my $buffer = new saga::buffer (10);
247                 my $ret     = my_file->read ($buffer);
248
249                 if ( $ret == 10 )
250                 {
251                     print "head: ", $buffer->get_data (), "\n";
252                 }
253                 else
254                 {
255                     printf "head: short read: %d \n", length ($buffer);
256                 }
257             }
258             else
259             {
260                 print "file $url is too short: $size\n";
261             }
262         }
263
264         if ( $@ =~ /^saga/i )
265         {
266             print "caught saga error: $@\n" if $@;
267         }
268
269         return;
270     }
271
272     -----
273     Example 2f: Fortran 90
274     -----
275
276     C Fortran 90 example
277     SUBROUTINE HEAD(session, url, buffer)
